THEELIN, (ketohydroxyestratriene) the first estrogen to be isolated in pure crystalline form and the first to assume clinical importance, is invaluable for alleviating the distress of the menopause and other estrogen deficiency states. A naturally-occurring estrogen, **THEELIN** relieves symptoms promptly *and* imparts a sense of well-being. Moreover, its notable freedom from side effects has long been familiar to physicians everywhere. Over two decades of clinical use and more than 400 references in the literature attest to its effectiveness.

The physical properties of **THEELIN** — solubility in oil and insolubility in water — have been utilized to prepare forms for administration that facilitate versatile therapy. **THEELIN IN OIL** is rapidly absorbed from the injection site. Absorption of **THEELIN AQUEOUS SUSPENSION** is slower and more sustained; the therapeutic effect, therefore, is produced over a longer period of time.

Both **THEELIN IN OIL** and **THEELIN AQUEOUS SUSPENSION** are available not only in individual ampoules, but also in Steri-Vials® for greater economy.

in bronchopneumonia:

Clinical responses in bronchopneumonia, Terramycin-treated, are characterized by the same promptness noted in primary atypical and lobar pneumonia. In a series of 31 cases there was "a good response in all cases, as manifested by the fall of temperature to normal in 24 to 48 hours, and by the improved clinical appearance of the patient." Follow-up x-rays made in 10 to 14 days "were completely negative or showed marked improvement."

MEDCOTRONIC

STIMULATOR MODEL 50

By means of the Medcotronic Pad Electrodes the current from the Stimulator is applied to individual muscles or groups of muscles, with comparative freedom of discomfort to the patient. Control of stimulation is attained by the operator regulating the type of stimulus provided, and the voltage and frequency of the current.

The Medcotronic Stimulator, Model 50, operates on 110 volt, 50 to 60 cycle alternating current. The current generated by the apparatus is non-sinusoidal alternating current. Output circuits have no direct connection to the power supply. The maximum voltage output is from 15 to 18 volts R.M.S. Write for a demonstration.

The $64,000,000,000 Question Is

Why do professional people think their accounts are different from other commercial accounts? Our answer is "No Difference."

Your customers have the same jobs or farms
Your customers have the same incomes
Your customers have the same debts
Your customers have the same habits
Your customers have the same excuses

Other commercial enterprises collect systematically, leaving the professional man holding the bag.

The wheel that squeaks gets the grease.

Psychological warfare commences immediately upon your forwarding your accounts for credit control and collection service. The services offered by the Professional Credit Protective Bureau Division of the I. C. System have been adopted by over 50 trade associations extending from coast to coast.
After twelve years in the liquidation of commercial and professional accounts receivable, you will be able to benefit by our experience.

Not a Collection Agency—All Monies Paid Directly to You

COST less than collection through your own efforts and in most cases one-half of the usual collection agency fees. Operates with extreme courtesy and goes to the fullest extent the law permits.

Our contention is that this is the outstanding credit control and collection service in the United States.

NO ASSIGNMENTS OF ACCOUNTS
RETAINS CUSTOMERS GOOD WILL

When you want money bad—we offer a service that is good!

Presenting

The Continental Professional Plan
OF ACCIDENT & SICKNESS INSURANCE

EFFECTIVE and OPERATING FOR
Members of your State
MEDICAL PROFESSION

DESIGNED EXCLUSIVELY
By CONTINENTAL CASUALTY COMPANY
One of the Oldest and Largest Stock Casualty
Companies in the World

A Few of the Many Outstanding Features

- ★ Monthly benefits for both accident and sickness payable FROM FIRST DAY — Minimum claim 7 days.
- ★ Pays monthly benefits for disability resulting from "accidental bodily injury": —the term "accidental means" is NOT used.
- ★ Pays monthly accident benefits regardless of whether disability commences within a certain specified time.
- ★ No automatic termination age.
- ★ The premium does not increase as you grow older.
- ★ House confinement is never required to collect full benefits.
- ★ Indemnities cannot be prorated because of other insurance or for performing duties of a more hazardous occupation.
- ★ Policies cannot be restricted by rider to exclude any disease or injury originating after date of issue.

Renewal is guaranteed to individual active members of the profession regardless of age, so long as the premiums are paid in accordance with the terms of the contract and the plan continues in effect for the members in your designated territory.

The Continental Casualty Company pioneered in the writing of Professional Association Insurance plans. The first such plan, written in 1923, is still in effect and the Company has never cancelled or declined to renew a Professional Plan because of unfavorable loss experience.

NOW available to all eligible members in active practice and under 69 years of age.
Plans A or B available to female members under age 65.

SICKNESS BENEFITS	PLAN AA	PLAN A	PLAN B
PAYS. . A Monthly Indemnity for total disability during first year, whether house confined or not, ... From First Day	$ 300.	$ 200.	$ 100.
PAYS. . Total Monthly Indemnity First 2 Years. . .	5400.	3600.	1800.
ACCIDENT BENEFITS			
PAYS. . A Monthly Indemnity for total disability during first year . . . . From First Day	300.	200.	100.
PAYS. . Total Monthly Indemnity First 2 Years. . .	5400.	3600.	1800.
PAYS. . Monthly Indemnity for partial disability up to 13 weeks . . . . From First Day	120.	80.	40.

The Cost is Low

	PLAN AA	PLAN A	PLAN B
Annual	$138.00	$92.00	$46.00
Semi-Annual	69.50	46.50	23.50

ADD $5.00 TO FIRST PREMIUM ONLY

From among all antibiotics, Internists often choose

AUREOMYCIN

Hydrochloride Crystalline

because

Aureomycin readily passes into the blood stream, whence it diffuses rapidly into all the tissues and fluids of the body.

Aureomycin is a broad spectrum antibiotic that has been shown to be effective in a wide variety of infections of bacterial, rickettsial and large viral origin.

Aureomycin has been reported to be effective in

Acute Amebiasis
Anthrax
Acute Brucellosis
Chancroid
Shigella Dysentery
Endocarditis*
Erysipelas
Granuloma Inguinale
Hepatic and Biliary Tract Infections*
Influenza
Leptospirosis
Lymphogranuloma Inguinale
Pericarditis*
Psittacosis
Q Fever
Rat-Bite Fever
Relapsing Fever
Respiratory Infections*
Rickettsialpox
Septicemia*
Rocky Mountain Spotted Fever
Boutonneuse Fever
Tick-Bite Fever
Typhus
Tick Typhus
Tularemia

*When caused by Aureomycin susceptible organisms.

Throughout the world as in the United States, aureomycin is recognized as a broad spectrum antibiotic of established effectiveness.

Capsules: 50 mg.—Bottles of 25 and 100. 250 mg.—Bottles of 16 and 100.
Ophthalmic: Vials of 25 mg. with dropper; solution prepared by adding 5 cc. of distilled water.

Still leading the active life –
RIGHT THROUGH THE MENOPAUSE
. . . oral estrogen therapy that imparts no odor, no taste, no aftertaste

WHEN you have replaced her confusion with understanding, you have eliminated one of her two major problems. The other—the actual physical symptoms—may be solved rapidly, effectively, esthetically with your prescription for SULESTREX. A water-soluble, stable, *pure* estrone salt, SULESTREX provides as effective therapy as science has yet created. It contains no urinaceous substances to taint her breath or perspiration, is odorless, tasteless, in tiny white uncoated tablets.

Clinical trials with SULESTREX have shown that response to the drug is constant, predictable and relatively free of side-effects. Following a study of 58 standardized menopausal patients, Perloff[1] reported SULESTREX a "potent and effective oral estrogen with an extremely low incidence of nausea." Complete control of symptoms was attained with from 0.5 to 4.5 mg. of SULESTREX daily—with a median daily dose of 1.5 mg. Write for complete information. SULESTREX Piperazine Tablets—available in 0.75-, 1.5- and 3.0-mg. potencies—are at all pharmacies. Abbott Laboratories, North Chicago, Illinois. Abbott

Meat...Its Place in the Dietary Management of Nephritis

The formerly held tenet that protein intake should be restricted for all patients with impaired renal function, in order to afford the kidney physiologic "rest," is no longer valid.[1] Except for infection and some neoplastic and traumatic disorders, the treatment of renal disease is nonspecific and essentially symptomatic. The clinical problem centers largely on diet regulation, in the hope of stimulating the kidneys to improve impaired function, without unduly risking harm.

Even in the presence of azotemia, a protein intake of 60 to 80 Gm. per day has not been found harmful to the renal patient. Low protein intake, on the other hand, together with urinary loss of protein may encourage the development of asthenia, anemia, hypoproteinemia, and edema.[2] Also pertinent to the dietary management in renal disease is the experimental finding that high protein diets in normal dogs promote higher urea clearance and greater renal blood flow than do low protein diets.[3,4]

Except in anuria, a protein intake adequate to maintain nitrogen balance has been suggested.[1] Although as little as 30 to 40 Gm. of protein per day may suffice for this purpose in the fever-free patient at bed rest, few occasions arise when 1 Gm. of protein per day per kilogram of body weight may not be given safely. In the presence of significant proteinuria, unless specifically contraindicated, the dietary protein may be increased beyond that amount in order to counterbalance the urinary protein loss.

Contrary to the still prevalent ancient belief among the laity, red meats are just as harmless to the renal patient as white meats; nor is there evidence that plant proteins are more beneficial in nephritis than animal proteins. As with the normal person, the dietary protein of the patient should be of high biologic value.

Meat, because of its high content of biologically complete protein, may contribute valuably to the protein needs of the nephritic patient. The nutritional importance of meat, however, is not limited to its contained protein. Meat also contributes highly significant amounts of iron and of the vitamin B complex, including niacin, pantothenic acid, pyridoxine, riboflavin, thiamine, and the newly discovered vitamin B_{12}. Other salient features of meat in the dietary of the patient are its high palatability, its stimulation of the digestive processes, its satiety value, and its easy and practically complete digestibility.

BELIEVE IN YOURSELF!

Doctor, you probably have read a great deal of cigarette advertising with all sorts of claims.

So we suggest: make this simple test...

Take a Philip Morris—and *any* other cigarette. Then,

1. Light up either one. Take a puff—don't inhale—and s-l-o-w-l-y let the smoke come through your nose.
2. Now do exactly the same thing with the other cigarette.

frozen
citrus
is as
NUTRITIVE
as
fresh

CITRUS JUICE ASSAY

Long welcomed in home and institutional kitchens for its convenience, economy and flavor—*frozen* citrus is now acknowledged the "nutritive equal" of fresh. The Council on Foods and Nutrition of the American Medical Association has declared* that—under modern processing methods—approximately 98 percent of the vitamin C content can be retained in the frozen concentrated juice. And, when properly stored (below its freezing point), there is practically no loss of vitamin C. Frozen citrus can thus be confidently recommended for diets at all ages, including infancy.

"PREMARIN" ®

Estrogenic Substances (water-soluble) also known as Conjugated Estrogens (equine).

"Premarin"—a naturally occurring conjugated estrogen—long a choice of physicians treating the climacteric—has been earning further clinical acclaim as replacement therapy in hypogenitalism.

In the treatment of hypogenitalism, the aim of "Premarin" therapy is to develop the reproductive and accessory sex organs to a state compatible with normal function.

Four potencies of "Premarin" permit flexibility of dosage: 2.5 mg., 1.25 mg., 0.625 mg., and 0.3 mg. tablets; also in liquid form, 0.625 mg. in each 4 cc. (1 teaspoonful).

"Premarin" contains estrone sulfate plus the sulfates of equilin, equilenin, β-estradiol and β-dihydroequilenin. Other α- and β-estrogenic "diols" are also present in varying amounts as water-soluble conjugates.

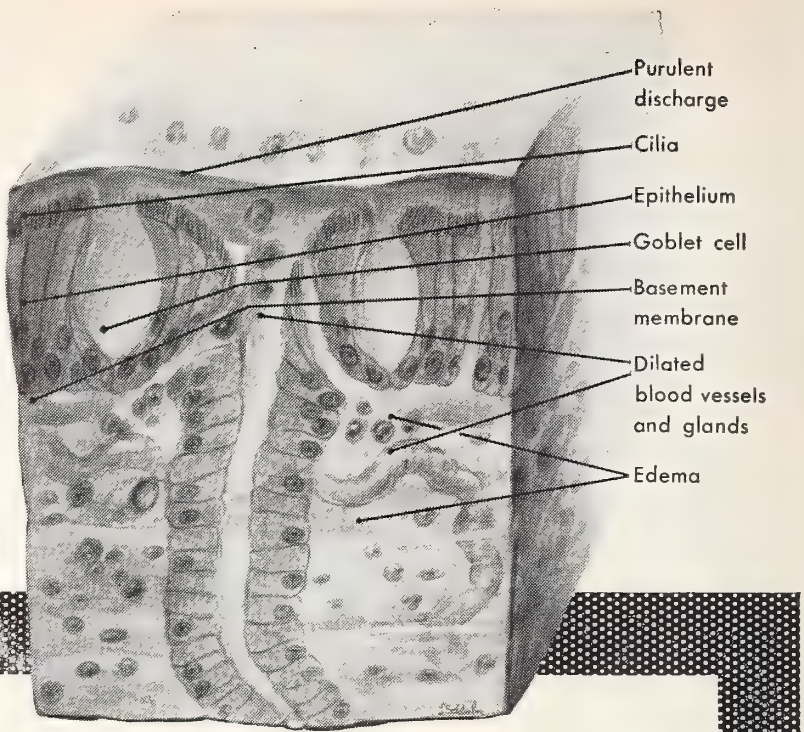
Neo-Synephrine

is....

"relatively nontoxic;
applied to mucous membranes
it reduces swelling and
congestion by contracting
the small blood vessels."

Council on Pharmacy & Chemistry:
New and Nonofficial Remedies.
1950, p. 218.



In acute or chronic engorgement of the nasal mucosa, Neo-Synephrine gives immediate relief.[1] It is effective within from 2 to 15 minutes and its action is sustained for 2 hours or more.[2]

In chronic conditions, Neo-Synephrine may be used once or twice daily over a period of weeks, with virtually no tendency to develop local sensitivity.[2]

The fact that Neo-Synephrine seldom produces central disturbances,[3] coupled with its effect in promoting aeration and freer breathing, makes it a drug of choice for use at bedtime.

Neo-Synephrine®

HYDROCHLORIDE

Brand of Phenylephrine Hydrochloride

how supplied

Only Terramycin in *Oral Drops* offers *all* these advantages

1

convenience of a liquid concentrate

Crystalline Terramycin Hydrochloride Oral Drops provide 200 mg. per cc., 50 mg. in each 9 drops—the only broad-spectrum antibiotic available as a liquid concentrate affording optimal convenience and flexibility in dosage schedules.

2

miscibility with foods and fluids

Terramycin Oral Drops are miscible with most foods, milk and fruit juices; can be taken "as is" or mixed. Potent oral drops offer rapid broad-spectrum antibiotic activity in a form permitting the utmost simplicity in the therapeutic regimen.

3

pure crystalline compound—well tolerated

Terramycin Oral Drops are prepared from pure crystalline material, free of impurities which may contribute to adverse reactions.

supplied:
2.0 Gm. with 10 cc. of diluent,
and specially calibrated dropper.

Extensive pharmacologic and clinical studies have amply demonstrated the remarkable hydrocholeretic action of DEHYDROCHOLIC ACID — Breon and SODIUM DEHYDROCHOLATE — Breon . . . Approximately three times the output of thin watery bile than that produced by an equal quantity of desiccated ox bile.

This hydrocholeresis promotes optimal drainage of the biliary tract . . . washes out mucus, inspissated bile, debris and inflammatory products and enhances T-tube drainage of the infected common duct.

DEHYDROCHOLIC ACID — Breon is indicated as adjunct therapy in chronic cholecystitis, noncalculous cholangitis, and certain other biliary dysfunctions, where no total obstruction exists.

SODIUM DEHYDROCHOLATE — Breon is indicated in cholecystography, to hasten appearance of the gall bladder shadow; and as standard test material for determination of arm-to-tongue circulation time.

In all cases requiring the fullest benefit from hydrocholeresis, prescribe and administer

DEHYDROCHOLIC ACID—Breon
Tablets — 0.25 Gm. each
FOR ORAL USE
Available in bottles of 100, 500 and 1000 tablets.

SODIUM DEHYDROCHOLATE—Breon
20% w/v Solution
FOR PARENTERAL USE
Available in 5 cc. ampules — boxes of 6 and 25.

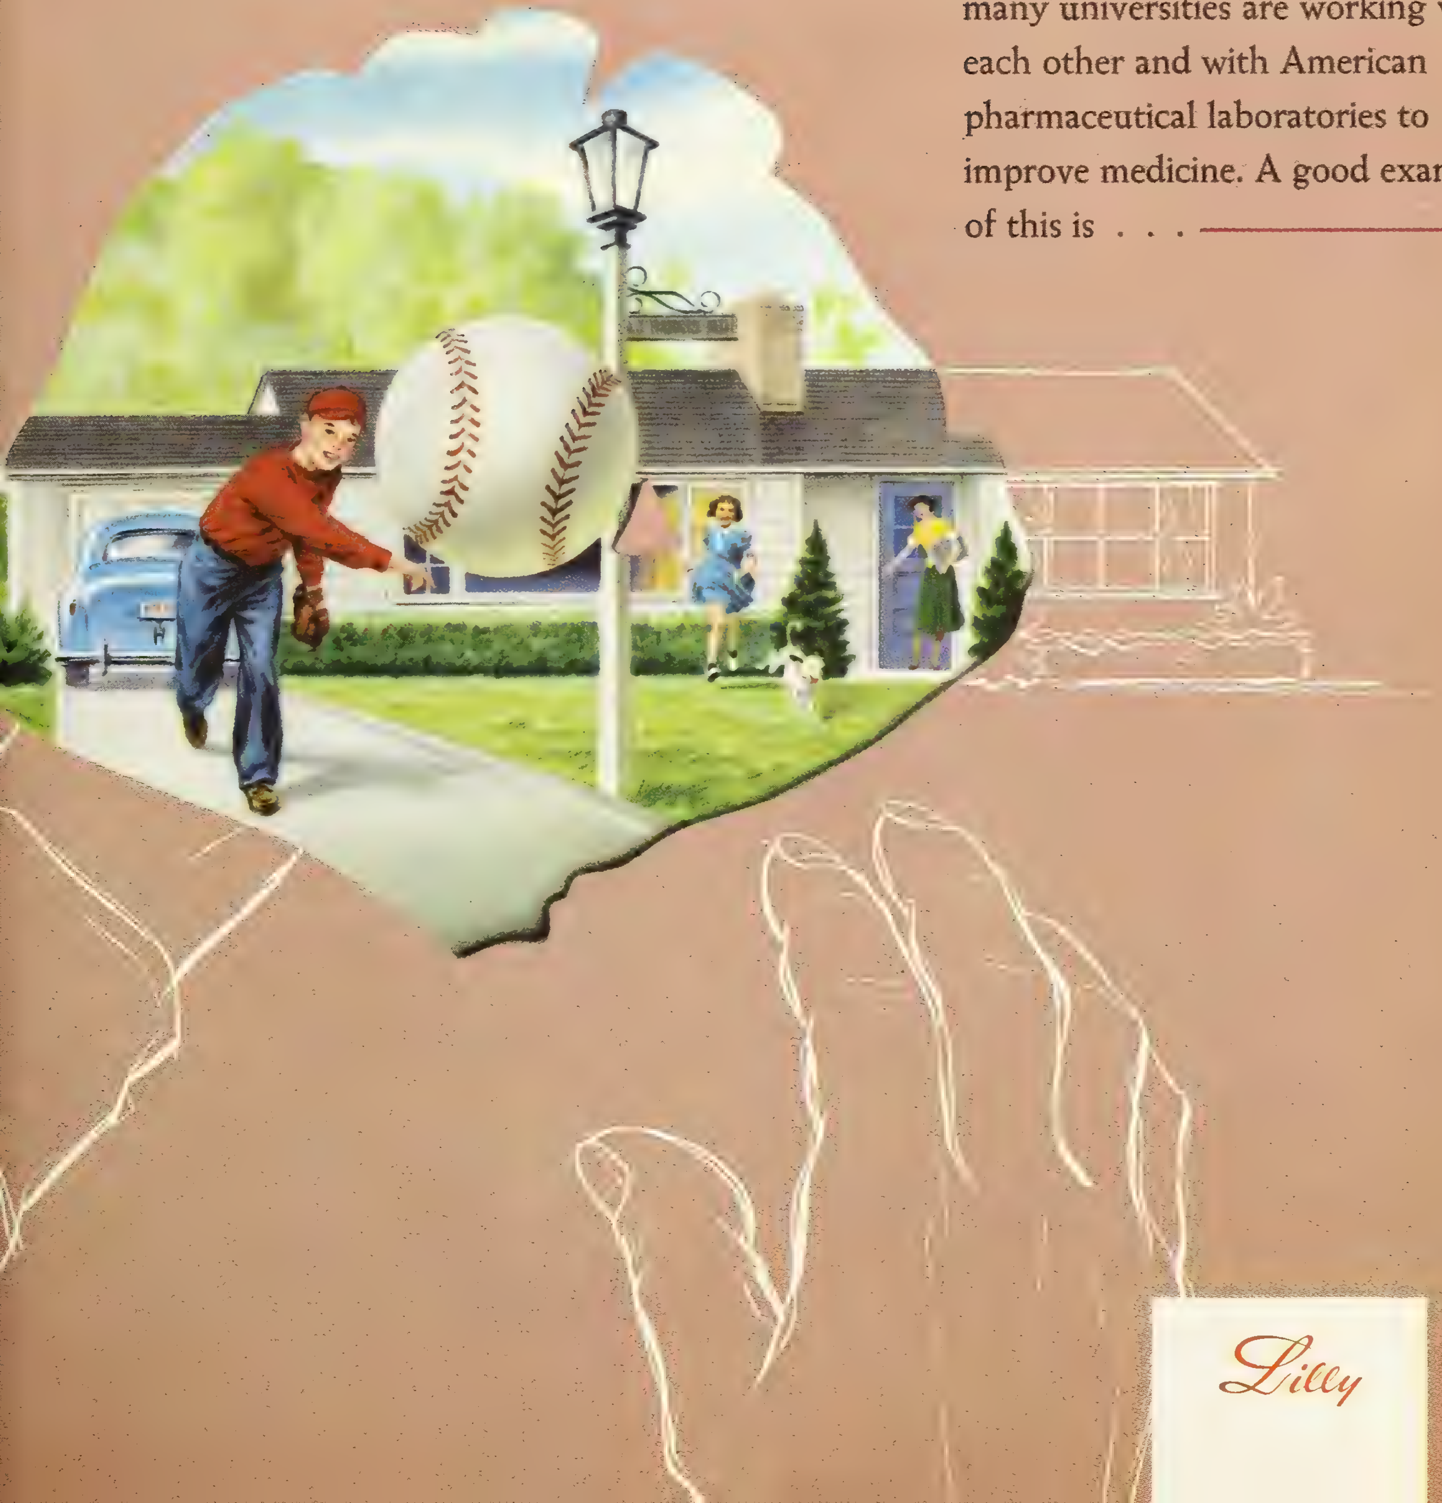
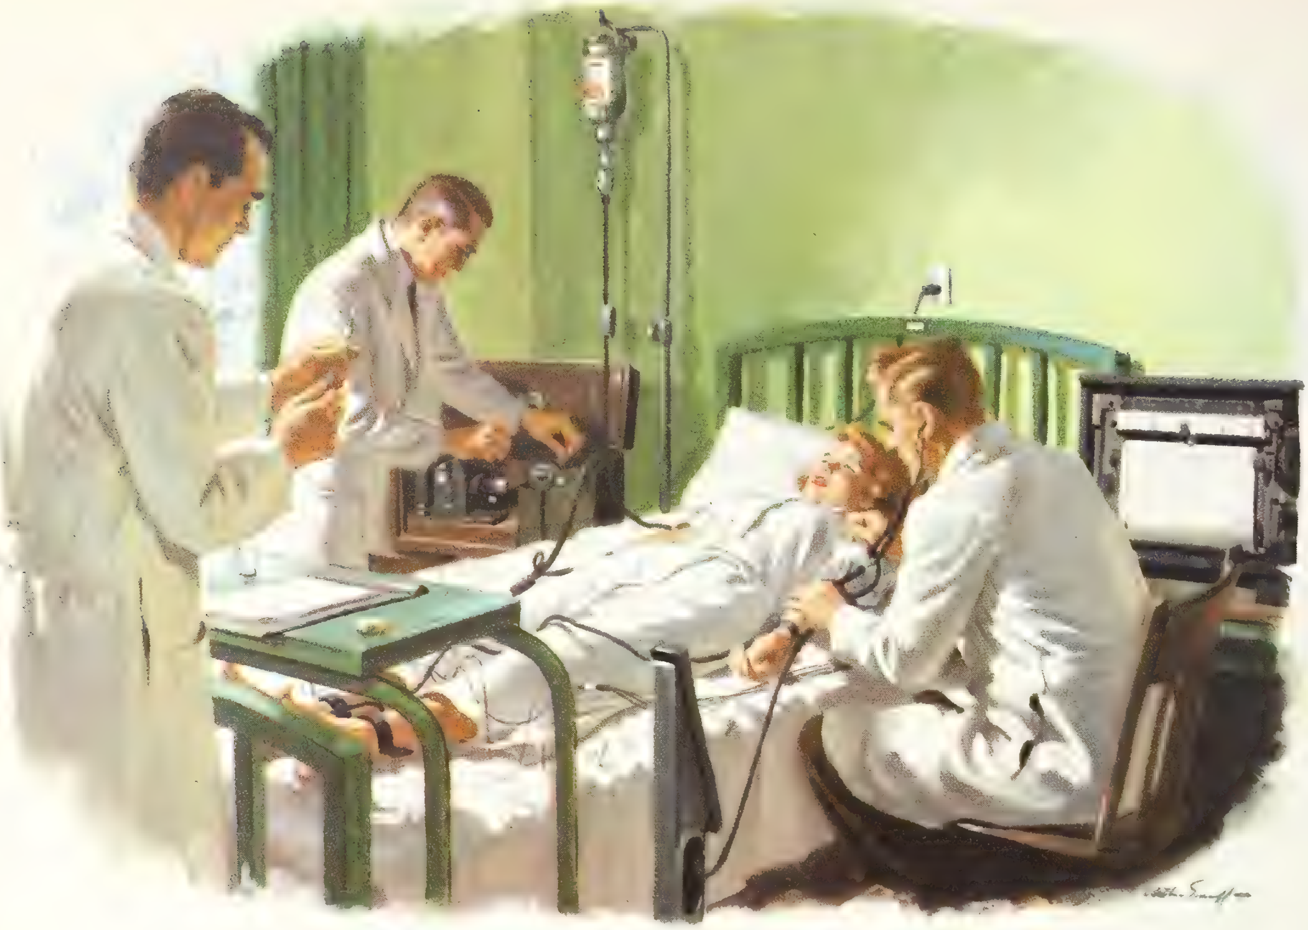
From Scrub-up to Scrub Fielder—

Dr. Harris must hustle to be even a part-time family man as well as a full-time physician. Lately, however, he sometimes has a little extra margin of time for his family—when he isn't seeing more patients than ever before. This is because many of his patients are getting well sooner, requiring fewer house calls, fewer office visits, fewer hours of medical care. Recoveries are faster now because of better methods and more effective medicines. Investigators in many lands and in many universities are working with each other and with American pharmaceutical laboratories to improve medicine. A good example of this is . . . →



Lilly



. . . the clinical-research team

A unique development in the organization of pharmaceutical research is attracting the attention of medical investigators all over the country and abroad.

As the last step before a product of Lilly research is submitted to outside investigators, it is thoroughly screened by a staff of Lilly research-clinicians. This careful preliminary study causes outside clinical investigators to welcome the opportunity of doing further research on products which already have been shown to be promising. The very broad extent of clinical study encouraged by this method gives positive assurance to practicing physicians. They can be certain that a product of Lilly research which finally has been released for general use will continue to provide successful therapy.

A MATERNAL SYNDROME ASSOCIATED WITH ISOIMMUNIZATION AND FETAL DEATH IN UTERO

IRWIN H. KAISER, M.D.

Minneapolis, Minnesota

THE fate of the fetus, rather than that of the mother, has up to now commanded attention in pregnancy complicated by isoimmunization. Except for the occasional sensitized mother brought to clinical notice by mismatched blood transfusion or afibrinogenemia,[5] it has been generally assumed that isoimmunization produces no recognizable symptoms and that laboratory determination of circulating antibodies is required for its recognition. Recent editions of two standard obstetrical textbooks either state that no clinical disease in the mother has been correlated with isoimmunization[2] or indicate that perhaps the incidence of toxemia is slightly increased.[3]

The three cases reported below represent instances of a striking maternal syndrome associated with grave degrees of isoimmunization. It is noteworthy that each patient presented herself to the physician with specific complaints. Both patients who had had previous fetal death in utero stated simply that they were experiencing a repetition of complaints associated with that event. The common clinical features in these three patients are a history of previous infant mortality due to erythroblastosis fetalis, the presence of high anti-Rh antibody titers, the sudden appearance prior to term of mild generalized and moderate dependent edema with sharp weight gain and the destruction of the fetus in utero shortly thereafter.

Case 1.—Mrs. H. L., a twenty-six-year-old woman, para 3-0-0-1, registered for the first time at Sinai Hospital, Baltimore, Maryland, on June 24, 1949, with an expected date of confinement of November 12, 1949.

In 1945 she had delivered elsewhere a baby which was in excellent condition at birth and which is alive and well today. In 1946 the patient was delivered at the same hospital of a living male infant. An abstract from that hospital stated that the baby was born without difficulty but almost immediately after birth began showing signs of abnormality. It had a weak cry and was noted to be markedly jaundiced. A diagnosis of erythroblastosis fetalis was made, and despite transfusion with Rh-negative blood, the baby expired. In the third pregnancy, which terminated in 1948, fetal movements ceased one week prior to delivery, which occurred three weeks prior to term. The infant weighed 8 pounds 2 ounces, but the only information that could be obtained from the hospital was that "the baby died before birth because of Rh-negative factor."

The patient gave no history of transfusion.

Examination of the patient's blood disclosed that she was blood group A_1 MN, Rh negative (cde). Antibody titers had been studied in the previous pregnancy and were elevated throughout that pregnancy. At the time of initial examination during the present pregnancy, elevated anti-Rh titers were again found. The patient's husband was found to be blood Group O Rh_0 (cDe). The husband's father was found to be an A_1, MN, Rh_2 (cDE), and the husband's sister, A_1, MN Rh_2 (cDE). The husband's mother was dead. It was, therefore, not possible to prove that the husband was homozygous.

Treatment with Rh haptene (Lilly) was initiated on August 2. Haptene was given once a week throughout August. There was no change in antititers. In the first week in September it was reported that the antititers had suddenly markedly increased. A few days after this observation the patient reported to the obstetrical clinic. She stated that fetal movements had suddenly become less and that the same pattern which had preceded her last fetal death in utero was appearing. The patient herself had noticed that two days previously she had begun to have edema in the lower extremities. She had increased 5 pounds in weight, from 100 to 105 pounds in

five days. There was no albumin of the urine. Blood pressure was 95/60. Despite the fact that the patient was two months from term, the fetus was estimated to weigh 2,600 grams. The fetal heartbeat was heard. X-ray of the abdomen was taken and was interpreted as showing slight edema of the fetal scalp. Epiphyseal centers were not found in the fetus. The patient was seen again a few days later, stating that she had felt no fetal movements for four days, and the fetal heart could not be heard at this time. However, the marked edema of the patient's feet and ankles was still present and the patient's face appeared pasty. She stated that she thought it was swollen. Her weight had increased another 2 pounds. About two weeks later the patient rather suddenly began to feel much better. Edema disappeared and she had a weight loss of 6 pounds, down now to almost the same weight she had been prior to the beginning of the episode. However, her appetite was poor.

She was followed for another week and a half, and finally on October 11, approximately four weeks following fetal death, the patient went into active labor. She delivered a macerated stillborn male infant weighing 1,700 grams without event. The post-partum course was entirely unremarkable.

Case 2.—Mrs. H. M., a thirty-year-old woman, para 2-1-0-1, registered for the first time at University Hospitals on October 31, 1950, with an expected date of confinement of April 26, 1951.

In 1942 she had a term delivery by low forceps of a 7-pound baby in excellent condition. Her second delivery in 1946 terminated spontaneously at thirty-eight weeks in the birth of a stillborn infant which weighed approximately 6½ pounds. She had noticed decreased fetal movements in the last weeks of pregnancy. About two weeks prior to the termination of this second pregnancy, the patient developed a deep burning itch of the hands and feet which vanished at the time of delivery. In 1949, at seven and one-half months of pregnancy, she spontaneously delivered a stillborn infant weighing approximately 5 pounds, which had had decreased fetal movements a few hours before labor began. With this third pregnancy, she had noticed itching of her hands, feet and other parts of the body which began three weeks prior to fetal death in utero.

The patient gave no history of operation or blood transfusion.

Laboratory studies revealed that the patient was Rh-negative (cde). Her husband was found to be Rh_2 (cDE) and hr″ (e) negative. Her living child was found to be Rh_2 (cDE) hr″ (e) positive. Her blood, titered against Rh_0 (D) cells, revealed no anti-Rh_0 (anti-D) antibodies. However, when it was titered against Rh″ (E) cells, high titers were found.

She was begun on Rh haptene (Lilly) in early November. Titers taken on blood in the last week of December showed marked increase in all the titers. The pregnancy proceeded uneventfully until January 6, when the patient noted the onset of itching of the palms and soles. She was seen very shortly after this. Physical examination was entirely unremarkable. The pregnancy seemed to be proceeding uneventfully. There was no albumin in the urine. The fetal heart beat was excellent in the left lower quadrant, and the patient had noticed no change in fetal movements. She was at this time approximately twenty-five weeks' pregnant. Haptene therapy was continued. On January 16 it was noted that the uterus seemed to be enlarging very rapidly. The patient was steadily gaining weight during this period. Fetal heart tones were good and fetal movements excellent. The itching continued without change. On January 20 there was a sudden exacerbation of the itching. She had gained 15 pounds in weight from 138 to 153 in the three weeks since the end of December. Fetal movements were felt the previous night, but none felt that day. It was difficult to be certain of the presence of fetal heart tones. The patient was given a prescription for phenobarbital and pyribenzamine on empiric grounds and two days later reported that the itching was much relieved. However, she had had no fetal movements in the last two days. In the last week in January the patient suddenly noted considerable swelling of the feet and ankles which lasted for about two days and was accompanied by a further gain in weight of several pounds. Study of the serum bile acids at the height of the itching on January 23 revealed a level of 1.3 mg. per cent against a control value of 0.8 mg. per cent.

The patient had three episodes of false labor. She was finally brought into the hospital on February 7, at which time she was essentially asymptomatic except for some brownish discharge. She had just lost 10 pounds. Induction was carried out successfully with the delivery of a 950 gm. stillborn infant. The placenta, which was obviously severely involved in hydrops fetalis, weighed 935 gm. and its delivery was accompanied by a 750 cc. third-stage hemorrhage. The patient was given a 500 cc. blood transfusion. Serum bilirubin done on the third day was 1.0 mg. per cent in one minute, 1.6 mg. per cent total. The patient's puerperium was entirely uneventful. She was discharged from the hospital asymptomatic and in good emotional state.

Case 3.—Mrs. L. S., a twenty-four-year-old woman, para 3-0-0-2, registered for the first time at University Hospitals on May 31, 1951, with an expected date of confinement of October 8, 1951.

In 1944 she gave birth spontaneously at full-term to an infant weighing 7 pounds 15 ounces without event. In 1945 she gave birth after an eight-hour labor to an infant weighing slightly over 9 pounds. These infants are living and well. She is said to have had a considerable amount of hemorrhage after each delivery, but it is not known definitely whether she had blood transfusion. In 1950 a term pregnancy which was complicated by elevated blood pressure and considerable edema terminated in the delivery of twins. One infant was noted to be jaundiced at birth and became worse very rapidly. Despite transfusion it died within forty-eight hours of delivery. The other infant was not noted to be jaundiced at birth, but it had a rapid drop in hemoglobin with an abnormal number of erythroblasts present in the blood, and despite an exchange transfusion done on the third day of life, the baby died on that day. Autopsy was performed on both infants and reported to be compatible with erythroblastosis.

The fact that the patient was Rh-negative was not ascertained until after this delivery.

Her living children were both found to be Rh_1 (CDe). Her husband was also an Rh_1 (CDe) homozygous for Rh′ (C).

The patient was found to have markedly elevated Rh antibodies on admission. She was followed in the out-patient department for the next several months. The fetal heart tones were first heard at the end of June. The patient received no therapy. She gained weight slowly to reach 250 pounds at the beginning of August. When she was seen in the out-patient department on August 23, approximately thirty-two weeks' pregnant, she was noted to have had a 5-pound weight gain. Blood pressure was still entirely normal and there was no albumin in the urine. Two weeks later, on September 6, 1951, the patient was found to have gained 15 pounds in the preceding two weeks. Fetal heart tones were present. There was a trace of albumin in the urine and blood pressure was within normal limits. Antibody titers had not changed materially. Hospitalization was advised, but the patient refused.

The patient appeared at the hospital at 5:00 a.m. on September 9 because of a sudden exacerbation during the night of severe generalized itching, which had appeared on September 6 but continued to get much worse. She had also had aching in the pelvis, nausea, a little bit of vomiting and generalized malaise. Examination of the urine disclosed 1+ albumin. Because of the patient's marked obesity, it was difficult to make out fetal size but the impression was that the baby was large. Fetal heart tones were present. Blood pressure on admission was 150/100. The situation was reviewed, and it was felt that fetal death in utero was imminent. It did not seem advisable to induce labor since the presenting part was floating and the cervix long and closed. It was, therefore, decided to terminate the pregnancy by cesarean section in an attempt to get a living baby. This procedure was carried out, with the delivery of a massively edematous, stillborn, 3,000 gm. infant with bilateral hydrothorax, ascites, generalized edema and a hemoglobin on the heart's blood of 3.6 gm. per cent. The serum proteins were found to be 1.8 gm. per cent. Autopsy on the infant was refused. The placenta was massive and showed the characteristic changes of hydrops fetalis.

In the twenty-four hours following delivery, the patient had a spectacular elevation of blood pressure which reached at its maximum a level of 220/150. This responded well to sedation and the patient at time of discharge had stabilized her blood pressure at 140/90. Examination of the eye grounds showed generalized arterial spasm with old choroiditis in the left eye in a patch of considerable size. The vascular spasm persisted for the entire hospital course. However, the albumin in the urine disappeared very rapidly after delivery and within twenty-four hours was absent. Study of the patient's circulating bile acids immediately prior to operation revealed a level of 1.5 mg. per cent against a control of 0.82 mg. per cent. The patient's bilirubin was entirely normal, producing an immediate reading of 0.1 mg. and a late reading of 0.3 mg. Pruritus disappeared almost immediately after delivery and did not reappear. The puerperium was otherwise uneventful.

Discussion

E. L. Potter, in her book on Rh, makes reference to a maternal syndrome associated with isoimmunization as follows:

> "There is a small group of women, however, who give birth to infants with hemolytic disease who show symptoms simulating toxemia but in whom the condition appears to be specifically related to the existence of hemolytic disease. In these patients pregnancy usually progresses normally until the seventh or eighth month, and then a sudden rapid increase in weight is associated with visible edema. A moderate amount of albumin is usually excreted in the urine. The systolic blood pressure almost never rises above 140. The fetus ordinarily dies soon after the onset of symptoms and is retained for varying lengths of time before it is delivered. We have not observed this syndrome in our series except in women who have previously delivered at least one other child with hemolytic disease."[4]

There can be little doubt that the three patients described above fall into this group. Mrs. H. L., the first of the three, fitted Potter's description exactly. Mrs. H. M., the second, while meeting all the other criteria, presented a new complaint. This pruritus, which was so persistent and which, the patient herself was convinced, foreshadowed the death of the fetus in utero, was never satisfactorily explained. The third patient in turn presented all these findings, and in addition, subsequently developed manifestations indistinguishable from severe acute toxemia of pregnancy.

The determinations of blood bile acids must be presented without comment. Although they were obtained in the search for a cause of the itching, there is no information as to normal or abnormal control values in pregnancy by the same method with which to compare them. The determinations of serum bilirubin make it appear unlikely that the itching is associated with jaundice.

It is certain that these are not the ordinary events of fetal death in utero. No such syndrome has been described in association with fetal death due to other causes,[1] and in patients with severe isoimmunization and fetal death in utero, the latter event ordinarily occurs in complete clinical silence. On the other hand, the observation of the present cases in a small group of sensitized wom-

(Continued on Page 31)

FETAL SALVAGE IN PREGNANT DIABETIC PATIENTS

T. PETRICK, M.D.
Saint Paul, Minnesota

As in all obstetrical problems in recent years, the question of maternal mortality has largely been pushed further and further into the background due to improved techniques for assuring maternal survival. The result has been an emphasis upon the search for methods of increasing fetal salvage. Because the survival rate for babies of diabetic mothers is known to be low, this field has produced extensive investigation and argument. The question resolves itself into three main points for purposes of exploration:

1. Control of the maternal diabetes.
2. Maintenance of intra-uterine life and delivery of living infant.
3. Survival of the infant in the neonatal period.

The first lies largely within the province of the internist. No attempt will be made to outline the problems of diabetic management. This, however, is of utmost importance to the fetus, as has been shown by many workers. Priscilla White[5] in 1943 said that "acidosis *per se* is not important as a lethal factor in producing fetal death." This has not been the experience of recent investigators. Hall and Tillman[1] have shown that the reverse is true. In their series of nine pregnancies exhibiting acidosis, six resulted in the loss of the fetus within a few days of the episode of acidosis. Although this is a small group, it has been the experience of others. For example, at the Charles T. Miller Hospital in a period of five years, eleven patients in acidosis at one time or another throughout their pregnancies produced only three living infants who survived the neonatal period.

Unregulated, brittle diabetics, because of known vascular changes, are believed to be more prone to all types of toxemia of pregnancy. This factor is responsible for an even lower fetal survival rate. To further emphasize the point, patients whose diabetes is under careful control have an incidence of toxemia reported to be between 30 and 50 per cent. In one notable exception, Reis[2] has reported a group of fifty-two diabetic women having seventy-two pregnancies, in which there were only six cases of toxemia. His group, however, contained very few patients having juvenile diabetes, or any patients whose diabetes occurred before the childbearing period. This would emphasize the point that patients with long-standing diabetes are more liable to have the antecedent vascular changes which predispose their type to toxemia. The most careful control and management is necessary throughout pregnancy in these patients to hope for a successful outcome.

Our second point, the maintenance of intra-uterine life to a point where fetal survival can be expected, is also intimately connected with the previous problems. A new approach to the problem was suggested by Smith and Smith.[3] It was their opinion that the administration of estrogenic substances during the course of a pregnancy increased the fetal survival. A further step in the right direction seemed to be taken when White[4] reported her studies on the "hormonal imbalance" of diabetic pregnancies and the possibilities of using stilbesterol to correct them. Over a period of fifteen years she reported 439 viable births with a fetal mortality of 18 per cent. These cases were subdivided into three groups: (1) Eighty-four cases with "abnormal hormone values which could not be corrected," (2) 297 cases with "abnormal values which were corrected," (3) Forty-seven cases with normal hormone values.

The fetal mortality rates for the groups were 42, 11 and 5 per cent, respectively. This work seemed to demonstrate once and for all that, in diabetics, with the use of stilbesterol, a definite and marked improvement could be obtained in fetal survival.

With the passage of time, certain inconsistencies have developed, and other contradictory evidence has been presented. Reis,[2] in 1950, reporting on his series previously mentioned, had a comparable viable birth mortality rate of 13.6 per cent, without the use of stilbesterol. Hall and Tillman[1] reported a fetal mortality of 18.2 per cent in diabetic mothers cared for at the Sloane Hospital for Women in New York City from

---

Read at the general staff meeting of the Charles T. Miller Hospital, Saint Paul, November 6, 1951.

Dr. Petrick is resident in obstetrics and gynecology at Charles T. Miller Hospital.

1923 to 1949. This mortality rate was also obtained without the use of stilbesterol.

It would seem pertinent at this point to quote directly from Reis' article:

> "The administration of stilbesterol in increasing daily doses is presumed to stimulate progesterone secretion, thus restoring the normal hormone balance and preventing immature and premature labor and toxemia of pregnancy. Recently Smith and Smith have shown that the administration of stilbesterol to normal, non-diabetic women resulted in larger, longer, heavier and more mature babies, with a definite decrease in the incidence of prematurity.
>
> "Sommers, Lawley and Hertig investigated the effects of this same stilbesterol therapy upon the weights of baby and placenta in the same group of women. They stated that 'weight of both baby and placenta are increased in stilbesterol-treated full-term and premature births' and that 'stilbesterol stimulates an increase in weight and presumably size of both infant and placenta.' They further found 'a more frequent occurrence of marked placental calcification and intervillous thrombosis in full-term stilbesterol-treated placentas and a definite incidence of mature chorionic villi and intervillous thrombi in the placentas of stilbesterol-treated patients who delivered prematurely.' "

He further states:

> "It is difficult to reconcile these reports. On the one hand, increasing and continuing administration of stilbesterol is used because it prevents immature and premature delivery, because it lowers toxemia, and, finally, because it is said to increase fetal salvage. Yet, in White's report, labor was terminated early in the vast majority of instances by cesarean section in the thirty-sixth to thirty-seventh weeks to prevent fetal overmaturation and placental overmaturation with their accompanying obstetrical problems of oversize and overweight fetuses and of fetal death in utero. On the other hand, the same increasing and continuing administration of stilbesterol is observed by Smith and Smith to result in larger, longer, heavier, more mature babies.
>
> "Furthermore, stilbesterol therapy would seem to be contraindicated in the diabetic, pregnant women to avoid rapid and early senescence of the placenta and to prevent some of the inexplicable fetal deaths in utero which are known to occur in the later weeks of pregnancy.
>
> "Further confusion concerning this entire problem results from a recent report by Davis and Fugo, who could find no evidence that stilbesterol stimulates production of steroid by the corpus luteum or the syncitium."

In the light of this, it is sufficient to say that our small series of twenty-six pregnancies in seventeen patients at the Miller Hospital had a fetal salvage almost exactly the same whether treated with stilbesterol or not. If any trend is apparent in our series, it would seem that the patient not receiving stilbesterol had a better chance to obtain a surviving infant.

With these things in mind, it would appear that the reasons originally proposed to validate the use of stilbesterol have not been borne out by either experimental evidence or improved fetal survival. Study of the literature, together with an analysis of our own experience, justifies the opinion that the administration of stilbesterol in the pregnant diabetic woman, as recommended by Smith and Smith,[3] offers little or nothing at all toward an improvement in fetal survival.

This opinion does not dismiss the well-known fact that infants of diabetic mothers have the unexplained propensity to expire *in utero.* Since this disaster tends to occur more frequently after the thirty-fifth week of gestation, the question arises as to the exact etiology. Is it due to the diabetes *per se?* Is it due to a greater incidence of toxemia? Further, if the infant survives to the point of parturition, is the poor fetal survival due to the tendency for infants to be greatly oversized, with resultant traumatic deliveries? With these thoughts in mind, it is understandable that many obstetricians believe that the fetal survival can be improved by delivery several weeks before term. There is fairly universal disagreement as to when and how the delivery should be accomplished.

In any obstetrical problem, there can be no absolute and set policy in the management of all patients. The number of variable factors, especially in pregnant diabetics, is too great to permit the establishment of an inflexible rule.

The proposal of one group, such as White's to section almost all patients a month before term, falls into such an inflexible category, ignoring as it does the possibilities of medical or surgical induction of labor in the proper patients as an alternative. White, in her series of 439 viable births, sectioned 75 per cent of her patients at about thirty-six weeks, for a fetal survival of 82 per cent. One-half of the fetal losses in this series, however, were in the neonatal period, indicating that prematurity may have played a large part in the failure of the infant to survive. Hall and Tillman reported 104 viable births with a fetal survival of 81.8 per cent. In this series only one patient in five was sectioned and then only for obstetrical indications. Only 10 per cent of their fetal losses were in the neonatal period. In a comparison of the two series, Hall and Tillman came to the conclusion that if they had sectioned fifty more patients according to the plan of White's they might have obtained five more living infants. Reis, in reporting his seventy-two viable births, sectioned about one-half of his patients. All of these section infants survived and the great majority of these operations were done at the thirty-sixth to thirty-eighth week.

On the basis of what has just been said, it would seem that a definite criterion can be established for the chance of delivering a living and surviving infant. One must deliver the infant by section or induction of labor before fetal death *in utero*. Since it is impossible to determine just when this catastrophe will occur in any given patient, the choice of the time and type of interference must be left to the obstetrician in charge.

The actual choice of the procedure for the individual case will depend upon physical findings, keeping in mind the added factors of toxemia and uncontrollable diabetes. The use of cesarean section at the thirty-sixth week enjoys the most universal popularity. This procedure, however, must only be done after the diabetes is well regulated. It would seem to us that the solution of this particular problem can be outlined in the following manner.

If the patient is a primipara, with what may be an oversized fetus, there is very little question but that the patient is best handled by cesarean section. This is assuming that the danger of delivering a premature child is ruled out by careful estimation of fetal size. It is admitted that the estimation of fetal size is uncertain at best. In the diabetic patient it is made more difficult by the presence of edema and hydramnios.

Cesarean section does not seem justified in patients who are suitable candidates for medical or surgical induction of labor. The indications for these procedures are multiparity, a well effaced and dilatable cervix and a well engaged vertex. Should these conditions be present at the thirty-sixth to thirty-seventh week, one is certainly justified in attempting delivery from below. The question of how to deliver the non-inductible multipara is a difficult one. From our studies we are led to the conclusion that the best course is to resort to cesarean section. When to do the procedure depends upon consideration of the factors previously mentioned.

Twenty-two pregnancies in our series of twenty-six reached the point of viability or beyond. Thirteen of those patients were delivered from below. In this group there were six stillbirths, two neonatal deaths and five surviving infants for a fetal survival rate of 38.5 per cent. Nine patients were sectioned, seven at thirty-six weeks, resulting in seven surviving infants for a 78 per cent fetal survival rate. This improved survival rate for section infants does not give a true representation of the problem, since all the very premature infants and those that died *in utero* were delivered by the vaginal route. If we eliminate all fetuses delivered or dead *in utero* before the thirty-sixth week, we arrive at a total of nine vaginal deliveries with five surviving infants.

Before discussing the third point of our paper, one interesting and vital point should be made and emphasized. It is now possible to make a flat, uncompromising statement that the incidence of congenital defects is not increased in the infants of diabetic pregnancies. In a survey of the literature in which such material has been reported, plus the cases from our hospital, compromising a total of 257 pregnancies, two major congenital defects were found. Both were forms of congenital heart disease. In addition, there was one case of hypospadias of minor degree. Thus with a maximum total of three congenital defects in 257 cases, the incidence is found to be one in eighty-six, the same figure reported for all normal, non-diabetic pregnancies. This cannot be too strongly emphasized to correct the older, unsubstantiated impression. This is certainly of vital interest to the diabetic patient contemplating pregnancy.

The last point of our paper deals with the survival of the infant in the neonatal period. In this, opinion seems to be fairly unanimous. All infants of diabetic mothers, regardless of size, mode or time of delivery, should be treated as prematures. The routine use of incubation, oxygen, oral or subcutaneous glucose and occasionally gavage seems to be the standard procedure. The difficulty of obtaining statistical evidence in favor of one form of therapy over another is increased by the additional factor of varying degrees of actual prematurity.

Experimental work with micro-sugar determinations shows that those infants have a faster, further drop of blood glucose than do infants of normal, non-diabetic mothers. Also, the return of the blood sugar levels to normal is slower in these infants than in the normal infants. The need for glucose, whether oral or subcutaneous, is obvious. Since these infants have an active sucking reflex and since they seem to retain oral feedings well, there is often little need for parenteral routes of administration. However, a minimum of fluid is to be used for administration, since some degree of dehydration is useful in treating these often edematous infants.

In summary, one can merely state that the problem of diabetes mellitus complicating pregnancy is serious. The solution to all the problems is not at hand. Improvement in fetal salvage in the diabetic patient demands constant observation, through care and regulation. This can be accomplished through vigorous action on the part of the internist, the obstetrician and the pediatrician.

A MATERNAL SYNDROME ASSOCIATED WITH ISOIMMUNIZATION AND FETAL DEATH IN UTERO

(Continued from Page 27)

en and Potter's prior observation of another group of similar patients make it appear likely that the syndrome is either being overlooked by students of the problem or being classified as an incidental acute toxemia of pregnancy. The symptom of pruritus, which is never associated *per se* with pre-eclamptic toxemia, indicates a definite difference between this syndrome and toxemia. Potter arrived at the conclusion that this is a separate entity without noting any instances of itching.

What is the explanation of this striking maternal hydrops? The data at the moment are inadequate to justify even a guess as to the answer. The edema does not differ from that seen in pregnancy under other circumstances. The most that the present report can hope to do is to stimulate detailed scrutiny of this syndrome, with the expectation that such study may aid in the clinical management of what remains an untreatable group among women with isoimmunization.

Summary

1. Three patients are presented who manifested a maternal syndrome in pregnancy complicated by isoimmunization. The clinical picture is characterized by a history of previously affected infants, appearance in the last trimester of sudden weight gain and manifest edema and subsequent fetal death in utero. Two of the three patients in addition complained of severe generalized pruritus, and one of these developed a severe acute toxemia following delivery.

2. It is suggested that this syndrome, while uncommon, is either being overlooked or being classified as toxemia of pregnancy. Since it appears to be uniquely related to the most severe form of isoimmunization complicating pregnancy, meticulous study of these particular patients is warranted.

3. At present, no explanation of the etiology of the syndrome can be offered.

POSTPARTUM HEMORRHAGE

E. C. SARGENT, JR., M.D.
Austin, Minnesota

THE subject to be discussed here is one which the majority of physicians have encountered in the past, and can reasonably expect to re-encounter. Eastman, in his textbook, states, "In modern obstetrics, no woman should die from postpartum hemorrhage.[3] This is a fair assumption, although no rigid set of rules can be formulated to guard against postpartum hemorrhage in 100 per cent of the patients. It would seem, rather, that certain precautions, together with steadily improving technique and new drugs, may be expected to bring us to an irreducible minimum of casualties.

Postpartum hemorrhage is defined arbitrarily as blood loss in excess of 600 cc. The rate of occurrence is in the neighborhood of 6 per cent, whereas blood loss in excess of 1,500 cc. is seen in about 1.5 per cent. Loss of over 2,000 cc. is present in .07 per cent and fatal hemorrhage occurs in about one delivery in every 3,300 patients. In a recent article, with an analysis of 6,000 deliveries, the average blood loss is reported to be 265 cc. in primiparae and 191 cc. in multiparae[2]. It was also shown that with episiotomy, or perineal lacerations, an additional average loss of 110 cc. occurs.

Predisposing Causes.—Predisposing causes can be divided into those under the direct control of the physician, and those beyond his control. In the former category are: operative deliveries, in which hemorrhage is three times more common; deep ether anesthesia; prolonged labor with maternal exhaustion; and, finally, mismanagement of the third stage. It has been said that the most common mismanagement of the third stage is in trying to hurry it.[1] In the latter group, that is, beyond the control of the physician, the most important predisposing cause of postpartum hemorrhage is the fetal size. The incidence of hemorrhage definitely increases with large babies, multiple pregnancy, and hydramnios.

Generally speaking, blood loss at levels of 600 cc. is not a serious matter. As mentioned previously, about half this amount is lost in delivery of an average primipara. It is worthwhile considering that when other conditions of blood loss exist, the loss of an additional 100 cc. or more from an episiotomy may be enough to put the patient into the hemorrhage group. Loss of 1,500 cc. is always a serious matter, and these patients must be carefully attended. An important point is that whereas a patient in good physical condition can withstand a considerable blood loss, another patient who has had an antecedent anemia, or one in whom prolonged labor has produced marked dehydration, may go into shock following the loss of a relatively small quantity of blood.

Etiology.—In order of frequency, the causes of postpartum hemorrhage are uterine atony, responsible for 90 per cent of the incidence; retained placental fragments, to blame in another 6 per cent; and lacerations of the birth canal. Of lesser frequency are rupture of pelvic varicosities, abruptio placentae, and placenta previa.

The first of these, uterine atony, is seen commonly following over-distention of the uterus, such as in the presence of an excessive-sized fetus, multiple pregnancy and hydramnios. Prolonged labor, as in primary and secondary inertia, frequently results in atony. Multiparity is another well-known cause. Fortunately, in all of these cases, the danger is predictable and preparations can be made well in advance in most instances to combat the atony if it develops.

Retention of secundines certainly occurs with great enough frequency to call for routine and careful inspection of the placenta. The finding of a placental defect or evidence of a succenturiate lobe is indication enough to prepare for intra-uterine inspection.

Most perineal lacerations are readily recognized and therefore do not constitute much of a problem. Many authorities suggest cervical inspection following all deliveries, but it is probably enough to undertake inspection only following the operative deliveries. The tears that extend into the fornices are quite dangerous, and even when diagnosed, the repair is one which requires infinite patience and care, with the bloody field and inadequate exposure.

From the Austin Clinic, Austin, Minnesota.

Presented at the annual meeting of the Minnesota State Medical Association, Rochester, Minnesota, May 1, 1951.

Clinical Picture.—Postpartum hemorrhage is seldom a massive outpouring of blood, but more often a steady dripping which on occasion may give a feeling of false security. The onset of shock develops commonly only after a period of a few hours, and often with astonishing rapidity. Pulse and blood pressure may compensate nicely for a time and then suddenly the pulse becomes rapid and weak, the pressure difficult to obtain, the patient experiences chilliness and air hunger, and, finally, loss of consciousness may supervene only shortly before death.

Diagnosis.—If bleeding follows completion of the third stage of labor, and if the fundus is firmly contracted, lacerations of the cervix and vagina must be sought for. The color of the blood aids in the diagnosis, with dark, venous blood more likely uterine in origin, and bright red blood probably from lacerations. Inspection of the cervix is definitely required following all operative deliveries. The passage of numerous clots, as well as sudden spurts of bleeding continuing after the fundus has firmly contracted down, will suggest retained placental fragments. Retained fragments plus accumulating clot in themselves may cause atony. In any event, if there is reasonable doubt, preparation for uterine exploration is made.

Once alerted to the possibility of hemorrhage, intravenous fluids are started at once. Cross-matching is carried out. An ampule of ergotrate and one of pitocin are given, the former intravenously. The operator obtains sterile gloves and gown while the perineum is being cleaned and fresh draping is being done. Light ether anesthesia or nitrous oxide will probably be required for exploration of the uterine cavity, though previous anesthesia may preclude the necessity for more. Deep anesthesia is contra-indicated. An assistant keeps up constant massage of the fundus, and, finally, the operator manually examines the uterus and removes any fragments found.

Following this procedure, if bleeding continues, if inspection reveals no lacerations and if the uterus shows no tendency to contract, the operator is forced to make a hasty decision. If shock is not too prominent a feature, if exhaustion and infection are not strong deterrents, and if the parity of the patient does not influence the judgment of the operator, a hysterectomy at this juncture may be a satisfactory solution of the problem. Short of this extreme are two much simpler alternatives, each with its own advocates. One is intra-uterine tamponade, widely practiced in this country; the other is bimanual compression of the uterus, long an established procedure in England, and steadily gaining adherents in this country. Tamponade, of course, consists of the placing of layer-on-layer of sterile gauze within the uterus, from above downward and with the greatest of caution. The alternate procedure, bimanual compression, is carried out by placing the fist of one hand within the vagina, snugly against the anterior uterine wall, while the other hand, on the abdomen, presses downward to meet the internal hand. This will effectively and immediately control the bleeding and it can be maintained indefinitely. The uterine pack can be used following curettage for incomplete abortion, but the relatively solid wall of a uterus at two to five months' gestation makes a better back-stop than a term uterus, especially one which has been previously distended, or thinned out from many preceding pregnancies, because of the inability of such a uterus to contract when forcibly distended. Those who argue against the pack contend that it is unphysiological, that it predisposes to infection, and that bleeding can actually occur between the pack and the uterine wall.

Finally, it might be well to review the management of the third stage. There is a fairly wide variance of opinion here, and no one technique will serve in all instances. Many favor giving oxytocics immediately after delivery of the head, others after delivery of the shoulder, and still others after delivery of the body. In breach presentations, it is unwise to administer any oxytocic until extraction is completed. Other authorities withhold oxytocics until completion of the third stage.

It is difficult to criticize any of the various methods, each seeming to produce results in the hands of its proponents. When ergotrate is given, it produces better results intravenously and should be given over a period of thirty seconds. If given after the delivery of the head, the attendant should wait for the stimulus to reach the uterus, and allow the contraction to aid in delivery of the body. It is argued that oxytocics employed at this stage speed up the separation of the placenta. It does seem that occasionally a placenta will be trapped by a firmly contracted uterus following too early usage of oxytocics. However, there

AN INVESTIGATION INTO THE ETIOLOGY OF NAUSEA AND VOMITING OF PREGNANCY

IRVING C. BERNSTEIN, M.D.

Minneapolis, Minnesota

BECAUSE of the great number of patients coming to the obstetrical service of the University of Colorado Medical Center with emotional problems, a psychiatrist has been assigned permanently to the service. After being on the service but a short time, the author was impressed by three observations: (1) that nausea and vomiting to some degree is such a common complaint, (2) that individual observers have such different ideas as to the etiology of the condition, and (3) that practically any medication or treatment is helpful.

Because of the vastly different concepts of the etiology, the author became interested in pursuing the subject further to see what additional information could be obtained toward establishing the etiology on a firmer basis.

The condition varies from a slight feeling of nausea on arising in the morning and a distaste for food to a condition of severe dehydration, inanition, and apparent toxemia. It is referred to in the standard textbooks of obstetrics as nausea and vomiting of pregnancy only until it becomes vicious enough to endanger life; then it is called hyperemesis gravidarum.[4,12,37]

A review of the English literature reveals that there are two schools of thought pertaining to the symptom. There are those who believe that the etiology is primarily organic, and there are those who subscribe to a psychogenic etiology with "feelings of rejection" being at the core of their theory.

The organic etiologies and their recommended treatments are multiple, and include disturbances of carbohydrate metabolism,[8,11,38] vitamin deficiencies,[39] endocrine imbalances, [34,35,36] protein intoxication,[5] various sensitization phenomena, including sensitization of the mother to the semen of the spouse,[9,21] reverse peristalsis of the gastrointestinal tract,[1] and unknown "toxins."[4,12,28,37] Although individually many of the investigators mention changes in the blood chemistry to substantiate their respective theory, their results have usually not been confirmed by other observers. Stander,[37] in summarizing these observations, states:

> "In general, it may be stated that there is little change in the mild but considerable in the severe. The changes in the severe may be attributed to dehydration and tissue destruction."

As can be surmised because of the multiple etiologies there are a multitude of treatments and remedies. These include hormones,[25,34,35,36] vitamins,[16,39] ultraviolet irradiations,[19] electrotherapy, [23] Dramamine®,[6] antihistaminics,[9] and various and sundry diets.[7,12,37] The treatments are particularly interesting in that they vary so much and yet that all the authors report phenomenal cure rates.

It must be quite obvious that no definite organic etiology or cure for this symptom has been discovered since so many authors have produced so many different theories and treatments.

Since no organic cause has been found to be definitely etiological in itself, it seems probable that an emotional factor may be involved in some degree in the development of this symptom.

The literature[4,12,37] mentions briefly that Kaltenback as early as 1891 believed that vomiting of pregnancy is usually a manifestation of a neurosis, somewhat allied to hysteria and readily amenable to suggestive treatment. Atlee also quotes Ferenzi in this connection:

> "The occurrence of intractable vomiting in early pregnancy, which has always been given so many toxicological explanations, is still more comprehensible to the psychoanalyst. One is dealing with a defense or rejection tendency, directed against what is unconsciously felt as a foreign body, but displaced (in the psychological sense) and carried out in regards to the gastric contents. Only in the second half of pregnancy, when the movements of the child no longer permit even the hysterical woman to deny the genital location of the changes and sensations does the inclination to vomit cease."

William Menninger[30] in a more recent article substantiated this statement when he wrote:

> "Vomiting of pregnancy is a more transparent symptom of rejection of pregnancy than many other neurotic

> symptoms . . . in my experience 50 per cent of obstetricians querried regard the symptom as psychologically motivated, another 25 per cent regard psychological factors as being very important."

One of the earliest clinical reports discussing the psychiatric treatment of nausea and vomiting of pregnancy and citing cases appeared in 1911. Sir Allan Hurst,[20] writing in *Lancet,* stated categorically that vomiting of pregnancy is always hysterical and that all cases can be cured by psychotherapy.

More recently the psychiatric literature has had many clinical reports of successful treatment of nausea and vomiting of pregnancy with some form of psychotherapy.

Flanders Dunbar[10] in an excellent review of the psychiatric literature in her book, *Emotions and Bodily Changes,* quotes many authors who believe the symptom is primarily psychogenic and that it can be treated successfully with some type of psychotherapy. These quoted authors explain that in some cases only suggestion is necessary while in others much longer and deeper forms of psychotherapy are indicated. This, of course, is in contradistinction to other writers who believe there are two types of nausea and vomiting—neurotic and organic—and cases are divided into these two groups on the basis of whether or not there is immediate response to suggestion.

In spite of the fact that many authors adhere strongly to their belief in an organic etiology for nausea and vomiting, the majority of them mention a neurotic component when they write of specific treatment. Beck,[4] who emphatically believes in a basic toxic etiology, states:

> "Suggestion should be liberally and seriously added to all measures."

It is obvious from the review of the literature presented that there are two schools of thought regarding nausea and vomiting of pregnancy. One considers the etiology as psychogenic, and the other considers the etiology as basically organic. As with all similar symptoms or illnesses, this sort of dichotomy is unrealistic and untrue. It does appear, however, from studying the literature that in most cases the most important factor in producing the end result is psychogenic and the most important factor in its alleviation is psychiatric. Stander,[37] who believes that the basic cause is toxic, says:

> "In the great majority of cases the toxic factor acts merely as a predisposing cause in neurotic women and becomes negligible after the nervous equation has been controlled. Neurotic vomiting makes up the bulk that we are called upon to treat."

Acceptance of the fact that nausea and vomiting of pregnancy is partially or wholly psychogenic does not mean that a patient having this symptom necessarily has a neurosis. In the author's experience this is one of the main reasons that the psychogenicity of this symptom is not "really" accepted by the physicians practicing obstetrics. These physicians do give "lip-service" to the concept but later will add, "I do not really believe it because my wife (or some close friend or my mother) had it, and I am sure she is not a neurotic." William Menninger[30] states, regarding this point:

> "The psychiatrist does not regard transient appearance of one or even several neurotic symptoms as indicating the presence of a neurosis, any more than râles are justification for the establishing of a diagnosis of pneumonia."

In other words, a single isolated symptom such as nausea and vomiting of pregnancy may indicate nothing but a transient unimportant disturbance or, on the other hand, a clinically severe pathologic condition.

Experimental Design and Results

The present study was conceived as an investigation to determine if patients with nausea and vomiting of pregnancy differ from those without the symptom regarding their feelings about five areas of their life: (1) pregnancy, (2) delivery, (3) marriage and family relationships, (4) children, and (5) spouse. From reading the literature, one gets the general impression that patients with nausea and vomiting are "neurotic" in their attitudes toward these areas while those patients without the symptom have "healthy" attitudes.

Patients for study were obtained from the obstetrical service of Colorado General Hospital and from employes and acquaintances of employes of the Colorado Medical Center. They were otherwise unselected. The only information given those who agreed to participate in the survey was that an investigation was being carried out on pregnant women, that it entailed seeing a psychiatrist for a short period of time, and that he would give them a psychological test.

TABLE I. COMPARISON OF GROUP I[*] WITH GROUP II[**] REGARDING TOTAL NUMBER OF RESPONSE INTERPRETATIONS IN THE TEST AREAS

		Pregnancy	Delivery	Family & Marriage	Children	Spouse
Group I	P	1		10	32	12
	R	12	7	12	10	20
	A	3		9	15	4
Group II	P	1	1	14	32	15
	R	13	9	19	11	25
	A	5		10	7	8

Key:
P—positive response
R—rejecting response
A—ambivalent response
[*] Those patients without nausea and vomiting of pregnancy.
[**] Those patients with nausea and vomiting of pregnancy.

TABLE II. COMPARISON OF GROUP I[*] WITH GROUP II[**] IN RELATION TO TOTAL NUMBER OF RESPONSE INTERPRETATIONS

	Group I	Group II
P	55 (37%)	63 (37%)
R	61 (41%)	77 (45%)
A	31 (22%)	30 (18%)
Total	147 (100%)	170 (100%)

Key:
P—positive response
R—rejecting response
A—ambivalent response
[*] Those patients without nausea and vomiting of pregnancy.
[**] Those patients with nausea and vomiting of pregnancy.

When the patient arrived for her appointment, she was given a series of twelve pictures and told to tell a story in her own words concerning what is happening in each picture, what led up to the picture, and what is going to happen.[*] The pictures were chosen because the author felt they would bring out more of each subject's feelings regarding certain aspects of her life better than direct questioning in a psychiatric interview.[**] Sometime during the interview the subject was asked a few identifying questions including whether or not nausea and vomiting was present during the first trimester of pregnancy and whether or not the pregnancy was planned. On the basis of the presence or absence of nausea and vomiting to any degree the subjects were divided into two groups of ten each: Group I—those without nausea and vomiting; and Group II—those with nausea and vomiting.

The responses were interpreted and tabulated by the author in relation to the various areas as being positive, rejecting, or ambivalent. There were no essential differences in the responses of the subjects in the two groups taken either individually or collectively. The latter is well brought out in Tables I and II. For example, in the group with nausea and vomiting taken as a whole there were 170 responses, with 37 per cent being positive, 45 per cent rejecting, and 18 per cent ambivalent, while in the group without nausea and vomiting there were 147 responses, with 37 per cent being positive, 41 per cent rejecting, and 22 per cent ambivalent. Whether the pregnancy was planned or not seems to have no bearing on the presence or absence of nausea and vomiting since the findings are about the same in both groups—six unplanned and four planned in Group I, as compared to seven unplanned and three planned in Group II.

Discussion

Since it is fairly well accepted that patients with nausea and vomiting of pregnancy are rejecting of certain aspects of their pregnancy, it remains to be explained why the data reveals that the group without the symptom are also rejecting and why the patients in this group do not vomit. As to why they do not vomit, two explanations are possible: firstly, the subjects in this group may have a higher vomiting threshold, which may well have both psychogenic and organic components; or secondly, these subjects may handle their feelings of rejection by other symptoms or through some type of acting out behavior. Concerning why the responses in both groups are so much alike, it is obvious that the common factor in both groups is a state of pregnancy.

Concerning "feelings" in "normal" pregnancy, Hirst and Strousse[18] write as a result of studying 100 pregnant patients as follows:

> "From this it may be deduced that most women are more anxious during the period of pregnancy and that the type of anxiety is chiefly conditioned by the economic and social group from which they were drawn. . . . The specialized types of anxiety were divided into four groups: (1) anxiety related to economic security, 75 per cent; (2) phobias, 16 per cent. . . .; (3) anxiety related to husband, 7 per cent. . . .; (4) anxiety relating to other members of the family, 10 per cent. . . . In the group of fifty cases adequately followed up after childbirth, even though the economic situation was unchanged, there was a definite lessening of anxiety in forty cases."

Apparently the patient's anxiety over the economic situation during pregnancy is just a manifestation of some underlying conflict.

---

[*] Based on the method of the "T.A.T." Morgan, C. D., and Murray, H. A.: A method for investigation phantasies: the thematic apperception test. Arch. Neurol. & Psychiat., 34:289-306, 1935.

[**] One of the patients was chosen by the author as a candidate for psychiatric treatment, and later it was noted that the feelings evidenced in the test were the ones that actually concerned her.

W. Menninger[30] emphasizes the point that multiple changes occur in a pregnant woman and that the result of these changes may be evidenced by other symptoms besides nausea and vomiting.

> "Even with complete willingness for the role there are so many changes in the physiological and social life of the woman that no prospective mother escapes from the emotional stresses that result from these changes. There are probably hormonal changes, which, even without a tumor of the abdomen, might theoretically account for some emotional changes from the normal. The pronounced readjustments required by this growing tumor—the disturbing of her activities and social relationships, the changes in her relationship with her husband, her wounded pride because of her 'deformity'—all are realistic causes for her emotional distress. The social status is an important determinant in the intensity of these maladjustments. For the social butterfly the 'figure' is all important; for the peasant laborer it is of no importance . . . in our culture even in the ideal situation of an intelligently desired pregnancy the woman may be expected to display some transient evidences of rejection or denial of the pregnancy. In every woman then we may expect positive and negative emotional attitudes to express themselves, sometimes fleeting, sometimes prolonged in duration—and these attitudes will be manifested in definite disturbances in her reactions and feelings. The specific reactions and disturbances may be understood only in terms of the life situation of that individual."

The author of this paper feels his experimental work validates Menninger's concept that all women are rejecting in some degree of their pregnancy, and that the effects of these feelings vary with the "life-history" and with the constitution of the pregnant woman concerned.†

The acceptance of this concept and the author's findings in accordance with it makes clear why some pregnant patients vomit and some do not, and why the labeling of the former as "neurotic" is not justifiable.

Summary

1. Nausea and vomiting of pregnancy occurs in one-half to two-thirds of pregnant women. It is called hyperemesis gravidarum when it becomes serious enough to endanger life.

2. The conclusion is reached from studying the literature that emotional factors, namely, feelings of rejection, are partly or wholly responsible for the development of nausea and vomiting of pregnancy and that the success in its treatment, reported by all authors, is due to suggestion.

3. Psychiatric study of ten patients with nausea and vomiting of pregnancy and ten patients without the symptom and comparing them individually and collectively reveals no essential difference in their attitudes toward important aspects of their life, namely, pregnancy, delivery, marriage and family, children, and spouse.

4. The explanation of the finding in this study that both groups react similarly to the areas tested is postulated as being due to the common factor in both groups—pregnancy.

5. The reason why one group manifested nausea and vomiting of pregnancy and the other did not, although both groups had about the same amount of rejecting feelings, may be explained as being due: (1) to different vomiting thresholds, or (2) to their handling their feelings of rejection through other channels.

6. The common practice of labeling pregnant women as neurotic just because they have nausea and vomiting with their pregnancy is not supported by this study.

VOLUNTARY INSURANCE GAINS

According to a recent report of the Health Insurance Council, at least half of the nation's population at the end of 1950 was covered by one or another type of voluntary protection against the economic hazards of sickness and accident. The Council is composed of nine trade associations in the life insurance and casualty fields, and its report indicates that all forms of voluntary health protection showed tremendous gains in the past year to score new records.

Hospital expense protection, which covers the largest number of people, was extended to 76,961,000 persons at the close of 1950. This total was 17 per cent greater than the figure of 66,044,000 just a year before. Growing public appreciation of the advantages of voluntary health protection can be seen in the fact that the number of people protected against hospital costs has more than doubled since the end of World War II.

Great strides also were made by surgical expense and medical expense coverages in 1950. Protection against surgical expense was provided to 54,477,000 persons at the end of last year as compared with 41,143,000 a year earlier, or an increase of 32 per cent. A year-to-year gain of 28 per cent was recorded by medical expense protection which covered 21,589,000 persons in 1950 and 16,862,000 in 1949. Both surgical and medical coverages also have shown larger postwar gains, with the 1950 number of persons in each case being more than quadruple the 1945 totals.

The over-all gains for the nation are reflected in the Empire State, according to the *United Medical Service Bulletin*. As of December 31, 1950, the number of subscribers was 1,948,904. This number had increased to 2,347,130 as of September 30, 1951, the latest available estimated figure.

Regarding amounts paid for medical care of U.M.S. subscribers for nine months of 1951, this figure stood at $10,563,449. Perhaps this sum may seem tiny in these days of billion dollar budgets, astronomic debt, and skyrocketing expenses, but it is nevertheless a considerable number of dollars. What does it mean in relation to costs of coverage?—Editorial, *New York State Journal of Medicine*, Dec. 1, 1951.

DERMATOSES OF THE LOWER EXTREMITIES

ISADORE FISHER, M.D.
Minneapolis, Minnesota

STASIS dermatitis and stasis ulcer are two of the most common skin conditions of the lower extremities. For that reason the bulk of this paper will deal with their recognition and treatment. Other cutaneous changes of the legs will be discussed briefly, chiefly in their relationship to the first two conditions mentioned.

Skin lesions of the lower extremities may be part of a generalized eruption or may be peculiar to the legs alone without a counterpart elsewhere on the body. Even those lesions which are part of a generalized condition may be modified by their location and differ considerably from lesions occurring on other surfaces. Dermatoses of the legs fall into groups similar to skin conditions occurring elsewhere on the body. An accurate diagnosis in all skin diseases is achieved by a careful consideration of the important primary and secondary lesions. There are certain primary and secondary lesions which are more applicable in the differentiation of lower leg dermatoses. These are multiform erythema, papules, vesicles, scale, hyperpigmentation and ulceration. Under these divisions will be found the dermatoses for consideration here.

Stasis in itself can have multiple causes, the chief one of which is interference with return flow from the legs because of incompetent veins. It is not my object to discuss the diagnosis of venous incompetence nor its treatment except insofar as it affects the skin. In the development of stasis dermatitis one may first see superficial red brown irregular macular pigmentation. The red color is due to extravasation of red blood cells within the skin. The color change is located principally over the medial lower leg especially about the medial malleolus, and extends proximally in a more diffuse fashion from that point. This discoloration ultimately is accompanied by a certain amount of scaling, atrophy, and in many cases verrucous change and edema. The dermatitis frequently becomes exudative as it becomes more severe and develops red exudative papules around the periphery of the large plaque. Stasis dermatitis is more commonly found on one lower extremity but may be seen on both. The course of the disease is not necessarily a gradual one such as outlined here and the process may be persistent at any one of these points. At any one time one may see marked deep brown pigmentation of the leg resulting from chronic venous insufficiency. Extensive vesicular eczema or a dry scaling lichenified eczema of the leg with or without accompanying edema may also occur. The subjective symptoms may be few though there generally is some itching, at times quite severe.

Stasis eczema generally follows an irregular course with remissions and exacerbations. In many individuals a gradual fibrosis occurs in the leg with induration of the affected area. This induration adds to the already existent venous impairment and acts as a constrictive bandage on the leg. The progression is a vicious one with increasing edema which eventually fails to disappear completely when the leg is elevated. Then follows the woody edema and elephantiasic change with verrucous hypertrophy. This later stage is the late chronic one and is usually irreversible. The development of ulceration is the next step.

These ulcers generally develop within the areas of chronic eczema or cellulitis due to poor nutrition. Varicose ulcers appear more commonly on the medial side of the ankle just above the malleolus. However, they may be seen at other points of the lower leg including the lateral side. The ulceration is frequently accompanied by the superimposed infection and by infectious eczematoid dermatitis. The ulcer may vary in contour from round to one with a polycyclic border that has sloping or undermined edges. The base is usually dirty, containing necrotic material or purulent discharge. The ulcer may be single or multiple and vary in size from a superficial abrasion to one that may encircle the leg and take in a good portion of the lower leg. In most instances the free border is at the same level as the surrounding skin but may occasionally have a firm fibrotic rolled edge. This latter development appears in the more chronic ulcers and in those which show little tendency toward healing.

From the Division of Dermatology, University of Minnesota, H. E. Michelson, M.D., Director.

Read before the Southern Minnesota Medical Association, Rochester, Minnesota, September 10, 1951.

In the differential diagnosis of lower leg dermatoses the most important of the multiform erythema group are the nodose lesions. The lesions of erythema nodosum are prone to occur on the extensor surface of the lower leg. They consist of brilliant, red, tender, often painful nodules which seem to blend into the surrounding skin, which is frequently edematous. These lesions go through a characteristic cycle, flattening out and becoming more livid. They may ultimately go through a color change which resembles a resolving hematoma. These nodose lesions may appear on the thighs, forearms, gluteal region and more rarely elsewhere. They tend to disappear within two weeks and leave no scar. The condition has been given a position of considerable importance because of its relationship to certain of the systemic diseases, namely, tuberculosis, rheumatic fever, streptococcal infections and coccidioidomycosis. Localized thrombophlebitis with its erythema, edema and tenderness also resembles erythema nodosum.

Whenever one considers erythema nodosum, the lesions of erythema induratum are brought into play. Erythema induratum appears in its own more distinct location on the posterior lower legs. It begins as deep-seated nodules which become increasingly blue in color and progress to ulceration. These deep-seated ulcers are very slow to heal. Erythema induratum is considered a chronic benign form of tuberculosis that occurs more commonly in young individuals with a greater incidence in females.

In the scaling papular group one finds a number of pruritic and nonpruritic conditions. The chief among these are lichen planus, psoriasis, and lichen simplex chronicus. Lichen planus is well known for its peculiarly violaceous polygonal papules which may occur in groups sometimes forming large plaques though the papules generally remain discrete. This is an eruption that generally has other components elsewhere on the body with a predilection for flexor surfaces and mucous membranes. Psoriasis is characterized by papules over which one finds a lamellar scale that is removed with some ease. Psoriasis also may have small guttate lesions or appear in large well-circumscribed plaques. The lesions of psoriasis are found more frequently over bony prominences, and in the scalp. The lesion of lichen simplex chronicus is represented by a well-demarcated plaque, which may be red or red-brown in color and is characterized by lichenification. The heavy scale may be a prominent feature. The principal symptoms are exaggeration of normal lines, thickening, and pruritus. When seen on the leg, the more common site is either above the lateral malleolus or in the popliteal area. This condition is most easily confused with stasis dermatitis.

The vesicular and bullous conditions of the leg are generally associated with similar conditions elsewhere on the body. The principal bullous lesions of the lower extremities are usually part of erythema multiforme, dermatitis herpetiformis, or pemphigus vulgaris. They are not readily confused with stasis dermatitis.

The last and possibly most important group consists of the conditions which are characterized either by ulceration or result in ulcerations of the leg. In passing only, one should mention such conditions as sickle cell anemia, scleroderma, and acrodermatitis chronica atrophicans. These conditions are in themselves rare and are not always accompanied by ulceration. The diagnosis of gumma always must be considered when a patient presents an ulcer of the lower extremity. Inasmuch as syphilis is a vanishing disease the presence of gumma is of lesser consideration. Certainly we should bear in mind that carcinomas can develop in any chronic ulcer. Ecthyma or traumatic ulcers do not have the accompanying signs of stasis ulcers.

The treatment of stasis dermatitis and stasis ulcer is dependent upon many factors. The most important one is correction of or support to the incompetent venous return. The vascular surgeon is better able to outline the criteria for the recognition of the various underlying conditions in varicose dermatitis and I shall not dwell on that. However, one must stress the need for correction of these factors. Correction may entail ligation of the greater and lesser saphenous veins with stripping and/or injection therapy. Many times ligation of the deep venous system may be necessary. Sympathectomy sometimes must be done in an effort to overcome the arterial and arteriolar spasm which often accompanies chronic venous impairment. From a dermatologic standpoint, however, one must point out that surgery alone will not always correct the cutaneous condition.

The dermatologic therapy is relatively simple. In the acute exudative process or infectious eczematoid dermatitis accompanying an ulcer, the best results are achieved with the use of continuous dermatologic wet compresses, rest and elevation of the extremity. At all times during the care of the acute process we are of the firm opinion that any secondary infectious factors should be eliminated. These include the care of mycotic dermatitis and good hygiene. The good hygiene tends to militate against the development of small areas of thrombophlebitis. In the acute weeping eczema wet compresses with either boric acid solution, Burrow's solution, Darier's solution or silver nitrate 1:1,000 are of value in clearing the acute process as well as controlling the infectious factor. After the edema is gone it is possible for one to go to a bland lotion or paint. Antipruritic lotions and ointments are of value. As soon as the patient is up and about good support is of greatest importance. For good support one needs a firm elastic bandage applied properly and worn throughout the time the patient is up and about and removed only when the patient retires for the night. After the infectious element and the exudative process is under control there is no better supportive measure than the Unna boot. It acts as an excellent supportive agent and prevents excoriation on the part of the patient.

Such measures as antipruritic and stimulating ointments as well as superficial x-ray therapy is sometimes important in the handling of stasis dermatitis. The role of x-ray and ointments is more important in the chronic fixed process.

The care of ulcers is more difficult because their presence indicates severe vascular damage and greater neglect on the part of the patient. The ulcer must first be cleaned up with the use of wet compresses. After the infectious element is cleared, good support as well as compression dressing of the ulcer is necessary in order to reduce the venous stasis and promote epithelialization. The type of compression bandage familiar to most everyone and commonly used is that employing a rubber sponge underneath a firm elastic bandage. There is some merit in the application of adhesive strips across the ulcer. The rubber sponge is then applied over it. The rubber sponge should extend beyond the sides of the ulcer and be held in place by a gauze bandage. Over this one should apply a firm elastic bandage. Some authorities stress the use of a heavy para rubber bandage extending from the toes to the knee with firm pressure over the sponge. It is not at all uncommon for one to apply an Unna boot to a leg that still has an open ulcer. I would say that support achieved with the boot is sometimes better than any other supportive measures utilized. The Unna boot is firm, elastic, gives clean support and stays in place without requiring any manipulation on the part of the patient. There are several commercially prepared bandages now available that have the gelatin impregnated within them and lend themselves to easier and cleaner application of the Unna boot. The bandage can be applied easily in the office and left in place for whatever length of time necessary. It can be removed and reapplied. After the ulcer is healed, good support must be maintained indefinitely.

More recently some degree of success has been achieved by the use of adenylic acid in an injectable form. My-b-den (Bischoff) is administered intramuscularly, giving 1 cc. every hour for five doses. This medication is carried out for about two days, at the end of which time the same drug is used as a suspension in gelatin and administered at daily intervals or every other day. There have been a number of instances in which the ulcer has been very resistant to treatment up until the time of the administration of this agent. Shortly thereafter the ulcer has proceeded to heal very rapidly. The total period of therapy varies up to three to four weeks.

The true solution to the problem lies in the adequate elimination of the underlying pathologic condition when and if possible. That elimination entails proper vascular surgery with correction of the stasis. These methods, meticulously carried out, will give the patients the best results one can offer for the present.

Every general hospital in this country, no matter how large or how small, can help eradicate tuberculosis in its own community. It can best do this by organizing and conducting its own tuberculosis control program. No other single agency has the opportunities for quickly finding and treating tuberculosis as has the general hospital. It has been estimated that every year about 16,000,000 persons are treated in general hospitals of this country and that 40,000 of them have undiagnosed active pulmonary tuberculosis. Since these unsuspected disseminators of tubercle bacilli are not adequately isolated, they defy tuberculosis control measures until diagnosed. Tragically, they are within a few feet of the diagnostic instrument which is not used. —SYDNEY JACOBS, M.D., *Diseases of the Chest,* November, 1951.

KYPHOSCOLIOTIC HEART DISEASE

Report of Five Cases

E. G. KIDD, M.D., New York, New York
and
JOHN FRANCIS BRIGGS, M.D., Saint Paul, Minnesota

THIS report concerns five cases of pulmonocardiac disease that are believed to be the result of deformity of the spine. An attempt will be made to show that the injurious effects exerted upon the heart by a marked kyphoscoliotic deformity may have their origin through involvement of either the greater or the lesser circulation.

Case 1.—A forty-seven-year-old woman was admitted to the hospital in 1948 because of increasingly severe dyspnea. Moderate exertional dyspnea had been present for a few years but had become subjectively handicapping only during the two months prior to hospitalization. Extreme deformities of the spine and rib cage had been present since the age of nine. Attempts at correction of these by various orthopedic procedures had failed. Other than the noting of muscular atrophy involving all four extremities and the very obvious bony deformities of the spine and thorax, little noteworthy was recorded on physical examination. The blood pressure was 116/80. An electrocardiogram contributed nothing towards a definitive diagnosis. Radiographic studies of the chest were difficult to interpret because of the marked angulation of the spine. Fluoroscopy, however, showed the lung fields to be clear. A few days following entry to the hospital, mental confusion and apathy, alternating with periods of excitability, developed. Following this, the patient lapsed into semi-coma and evidenced a Cheyne-Stokes type of respiration. The use of digitalis and oxygen caused no improvement, and she rather rapidly expired. Post-mortem examination revealed a pronounced dilatation and hypertrophy of the right ventricle. The lungs were moderately congested and quite emphysematous in appearance. The angulation of the spine was so marked that the bodies of the mid-dorsal vertebrae were in contact with the right lateral chest wall.

Case 2.—A forty-seven-year-old man was hospitalized in 1946 with complaints of recent onset of rather severe headache. Directly following this, he had developed cough, fever, dyspnea and marked fatigability. He had had a severe bout of what had been termed "bronchitis" ten years previously and at the age of eight was said to have had poliomyelitis. A marked spinal deformity had developed following the childhood illness. The examiners noted a thin, asthenic individual who was orthopneic, cyanotic and subject to paroxysms of cough. The lungs were congested and the neck veins engorged. The blood pressure was within normal range. The patient expired thirteen hours after admission to hospital despite the use of oxygen and penicillin. Chest x-ray had shown an indeterminate type of infiltration in both lower lung fields. At autopsy, the aorta was found to follow a markedly angulated thoracic spine, but no reduction in the caliber of the aortic lumen was demonstrable. The right ventricle was hypertrophied and the circumference of the pulmonary ring was 1 centimeter greater than that of the aortic ring. A purulent-bronchitis, bronchiectasis and adhesive pleuritis were present. A fibrous pleuritis was found in both pleural cavities.

Case 3.—A twenty-four-year-old man had a kyphoscoliotic deformity dating back to an attack of poliomyelitis at the age of fifteen. An allergic asthma had been present since infancy and, following the development of the rib cage deformity, had become more troublesome. Physical examination fifteen months prior to death disclosed the presence of chronic dyspnea and a tinge of cyanosis. A diastolic murmer was present at the cardiac base which was transmitted down the left sternal border. This murmer could be altered in intensity by changing the contour of the thoracic cage. The blood pressure was not abnormal. Roentgenologic studies showed enlargement of the pulmonary conus area and there was fluoroscopic evidence of emphysema. The P waves in limb lead II of the electrocardiogram were suggestively peaked and the T in precordial lead IV was inverted. Dyspnea became increasingly more pronounced, and the terminal episode was essentially that of pulmonary insufficiency with failure of the right heart. At necropsy the significant findings included marked dilatation and hypertrophy of the right ventricle, dilatation of the right auricle, and the presence of a bicuspid pulmonary valve. The bicuspid valve did not appear to be functionally insufficient. The right lung was markedly compressed and the left lung emphysematous.

The last two cases illustrate a different set of circumstances that may conceivably exist in kyphoscoliotics.

Case 4.—A thirty-two-year-old switchboard operator, when first examined in 1933, complained of cough, dyspnea and pain in the chest of a pleuritic nature. She was a small thin woman with a marked kyphoscoliotic deformity which dated to a childhood poliomyelitis. During a seven-year period of observation, blood pres-

---

Read before the Minnesota Society of Internal Medicine, Minneapolis, Minnesota, May 26, 1951.

Dr. Kidd was formerly a resident at Ancker Hospital, Saint Paul, and is now a resident at the Hospital for Special Surgery, New York, N. Y. Cases reported, for the most part, were studied at Ancker Hospital.

Dr. Briggs is clinical associate professor of medicine, University of Minnesota.

sure readings varying between 150/100 to 250/150 were recorded and one episode somewhat suggestive of hypertensive encephalopathy had occurred. Chest x-rays taken in the routine postero-anterior view were rather uninformative due to the extreme kyphosis and angulation of the spine. Death was apparently precipitated by a respiratory infection which had been accompanied by increasingly severe dyspnea. At autopsy all of the cardiac chambers were found to be dilated and the left ventricle hypertrophied. The lungs appeared to be compressed and the lower lobes were atelectatic. The aorta was found to follow the spine, which was markedly angulated. At the most acute angle, there was a definite and marked reduction in the caliber of the aortic lumen. It was postulated at the time of autopsy that this mechanical effect might have been partly or wholly responsible for the hypertension. Unfortunately, none of the confirmatory clinical evidences of this "coarctation-like" effect had been recorded during life. Renal insufficiency, at least to any marked degree, had apparantly not developed. Microscopically, the vascular changes in the kidneys were not too prominent and fairly well excluded any primary renal origin for the hypertension. These microscopic findings, however, could be considered quite compatible with those observed in essential hypertension.

Case 5.—A twenty-four-year-old chemist, seeking medical advice for an incidental complaint, afforded the opportunity of recording a somewhat similar variant of the kyphoscoliotic syndrome. He had developed spine and rib cage deformities following a tuberculous infection of the spine and hip during infancy. At the age of six, his parents had been told that he had a "heart murmer." At the age of eighteen, hypertension was found on routine physical examination. This finding has since been moderate in character but definitely sustained. No symptoms referable to the cardiovascular or respiratory systems have developed. On examination there were soft systolic murmurs at the apex and base and also a blowing diastolic basal murmur. This diastolic murmur has since been noted to be evanescent in character. The femoral pulses were barely discernible. The blood pressure in the arms varied from 150/100 to 170/110. In the legs a pressure of 90/60 was found on the right and no reading was obtainable on the left. There was x-ray evidence of an extreme degree of rib-notching and of moderate left ventricular enlargement. No significant electrocardiographic abnormalities were present. Exploratory thoracotomy was carried out in May, 1949, and it was found that the aorta had a normal caliber to the point where the descending portion joined the spine. At this level, which was below that of the ligamentum arteriosum, the size of the aorta was rather suddenly reduced by approximately one-half. Below this point the aorta remained narrowed to at least the level of the diaphragm. The left subclavian artery was dilated to approximately the same size as the aortic arch. The surgeon noted the presence of enormously dilated vessels about the tip of the scapula as he made his entry into the chest. No definitive surgical procedure was feasible, and to date the status of this patient remains unaltered.

In evaluating thoracic deformity as an etiologic diagnosis of heart disease, the deformity should be great enough to cause either direct mechanical interference with the heart action itself or interference with blood flow in the aorta or the pulmonary circuit.[4] The first three cases cited are believed to be examples of cor pulmonale due to interference with the dynamics of the lesser circulation. In the literature on kyphoscoliotic heart disease, the protocols presented appear to be concerned nearly entirely with this type of situation.[1,3] The rib cage deformity in itself must encroach upon functioning lung volume to some extent. However, it is a good assumption that this deformity brings into play a secondary chain of events that further hamper pulmonary function. A fixed distorted rib cage and restricted diaphragmatic movement results in a cough of poor expulsatory force. This sets the stage for the development of atelectatic pneumonitis, bronchitis, bronchiectasis, bronchopneumonia, adhesive pleuritis and pulmonary fibrosis. These are common developments in kyphoscoliotics, and they all serve to further reduce the vital capacity, to increase the ratio of residual air to vital capacity and to promote the formation of emphysema. Thus the primary difficulty with these patients is that of pulmonary insufficiency. The failure of the right heart, if it develops, is only a secondary event.

As in the presence of severe idiopathic pulmonary emphysema, it should be remembered that the use of respiratory depressant drugs or of continuous oxygen therapy may be very hazardous by interfering with carbon dioxide elimination. Any respiratory depressant may increase the already existing difficulty. The continuous use of oxygen may take away the only stimulus the patient has left to respiration, namely, the oxygen want. Both of these therapeutic agents may then produce a severe respiratory acidosis with rise in cerebrospinal fluid pressure—an event that may well have a fatal outcome.

It should also be pointed out that many of the kyphoscoliotic deformities develop during childhood. It is stated that the lungs of some adults who developed the spinal deformity during childhood have the appearance of infantile lung tissue.[3] The life span of childhood kyphoscoliotics is relatively much shorter than that of those who develop the deformity during adult life. There is at least some evidence indicating that lung tissue during the growth period can actually regenerate itself if called upon to do so, whereas in the adult the lung has only to resort to the formation of emphysema when its ventilatory function is hampered.[2] This is only one of the many reasons for attempting to prevent and correct the spine deformity as early in life as possible.

The outstanding feature of the last two cases is the presence of hypertension. In the autopsied case (Case 4), the clinical evidence that stenosis of the aorta was responsible for the blood pressure elevation is very unfortunately lacking, but the post-mortem studies suggest that such might have been the case. The clinical findings and the observations made at thoracotomy in the last case offer convincing evidence that a coarctation-like effect was in operation. The assumption is made that the hypoplastic aorta developed during the growth period as an accompaniment of the angular deformity of the spine. This, of course, is pure speculation and does not at all exclude the possibility that the malformation of the aorta was congenital in origin. There are very few cases of this kind on record, and those that have been presented are far from convincing in attempting to demonstrate the connection between the kyphoscoliosis and hypertension.

The life span of those kyphoscoliotics who develop pulmono-cardiac difficulties is shortened. This clinical observation was first made by Hippocrates. In his forty-sixth aphorism he states that "such persons as become hump-backed from asthma or cough before puberty, die." Many kyphoscoliotics may live to a ripe old age. This observation was also made by Hippocrates, i.e.: "and in those cases where the gibbosity is above the diaphragm, they become affected with difficulty in breathing. And yet many of them have borne the affection well and have enjoyed good health until old age, more especially those persons whose body is inclined to be plump and fat; a few of them lived beyond sixty years of age, but the most of them are more short-lived."

POSTPARTUM HEMORRHAGE

(Continued from Page 33)

seems little argument that the blood loss is minimized with early usage of pitocin.

If the placenta does not separate readily and bleeding appears to be excessive, one should attempt to express it. The uterus should not be handled too vigorously, however, as fingers pressing into the wall may cause serious damage, as well as causing irregular separation of the placenta at times. Pressing downward on the fundus has also been known to cause inversion when done too forcibly. Gentle kneading of the fundus is preferred, and downward pressure of the fundus to the extent of delivering the presenting edge of the placenta to the vaginal outlet is perfectly acceptable.

Another difference of opinion exists over management of the third stage when the placenta fails to deliver within a few minutes. Many contend that as long as bleeding is absent, the placenta can be left indefinitely. The greatest extreme to this is routine manual removal. It seems best to adopt a middle-of-the-road course, which would appear to be manual removal at the end of an hour (or after estimated blood loss of more than 400 cc.), all else failing. With antibiotics available, the procedure can no longer be condemned, and can be carried out with safety.

THE ECONOMIC VALUE OF HIGH QUALITY MILK

MYRON W. CLARK
Saint Paul, Minnesota

IT takes high quality milk to produce good dairy products, but sometimes we are slow to recognize the economic value of that high quality milk. When we speak of economic value, we think of dollars and cents. Let's take a look at the record. In 1950, we produced in Minnesota 8,253 million pounds of milk. Forty-four per cent of this was sold as cream. The records show that 105,721,698 pounds of butterfat was purchased in Minnesota as sweet cream; 33,948,673 pounds of butterfat was purchased in Minnesota as Grade 1 cream; 3,861,879 pounds of butterfat was purchased as Grade 2 cream. It is required in Minnesota that at least three cents differential be paid between grades of cream. On the basis of a three-cent differential, had the nearly four million pounds of butterfat in Grade 2 cream and the nearly thirty-four million pounds of butterfat in Grade 1 cream been of high enough quality so it could have been purchased as sweet cream, the farmers who produced it could have pocketed over $1,260,000 in additional income.

As a further example, about 46 per cent of the 1950 production of milk in Minnesota was sold as whole milk. Again a look at the record shows 21,686,275 pounds of butterfat was purchased from producers as market milk, what we generally think of as bottling milk; 102,336,763 pounds of butterfat was purchased in Grade 1 milk; 10,878,428 pounds of butterfat was purchased in Grade 2 milk. Had the producers of this milk been sufficiently informed and equipped and taken care enough to have kept this Grade 2 milk in the Grade 1 class, they could have enriched their coffers to the tune of more than thirty-one million dollars, and by some stretch of the imagination if we could assume that a sizable portion of this Grade 1 and Grade 2 milk could have been marketed as Grade A market milk, the economic advantage to the producer would have been astounding. At present prices, even a small producer with 600 pounds of milk per day can receive an additional $100 a month if his product is Grade A. I think these figures indicate that high quality milk has real economic value to the producer.

We have done a creditable job of increasing production of dairy products. We have seen the production possible from one animal increase again and again until one cow has produced more than 41,000 pounds of milk a year. This very year we are producing more milk than at any other time in our history from fewer cows than we have kept for milk in any of the last twenty-five years; however, with the rapid strides and advancement that we have made in production, we have not kept pace in the quality improvement we have maintained in our dairy products, and it behooves each of us to make a greater effort along this line.

It is in the economy to the processor that the real value of high quality dairy products shows up. By way of comparison, the State of New York and the State of Minnesota have about the same number of cows kept for milk, yet the farmers of New York received last year $142,500,000 over that received by Minnesota farmers for the products of those cows. The average price paid per 100 pounds of milk in Minnesota was $2.57, while in New York the average price was $4.04. Certainly there are many other things besides quality which affected this great difference in price, but in the high competitive world in which we live, we must maintain high quality in order to insure a market for our products. For the great quantities of dairy products which we produce in Minnesota, we must find a market for more than 80 per cent of these products outside of the state, and these out-state markets which have become highly competitive are based on quality.

The National Conference on Interstate Milk Shipments, which sets up standards and agreements by which milk and milk products are shipped from one state to another, leaves no doubt in our mind that if we as a state are going to cultivate the markets we must have, it will come only through maintaining high quality.

High quality milk has economic value to the consumer. A spokesman for U. S. Public Health

(Continued on Page 72)

Read at the Public Health Conference held at Minneapolis, Minnesota, September 28, 1951.

Myron W. Clark is commissioner, Department of Agriculture, Dairy and Food, State of Minnesota.

Presentation of Distinguished Achievement Awards

To Medical and Nursing Graduates of the University of Minnesota

DURING 1951, the centennial year of the University of Minnesota, the several schools and colleges of the University were authorized by the Regents to nominate certain of their graduates, not currently associated with the University, for Distinguished Achievement Awards. The presentation of these awards was made to graduates of the Medical School and affiliated units of the University at a special faculty dinner held October 8, 1951 in the ballroom of Coffman Memorial Union. This ceremony, which was attended by almost 500 persons, was a delightful occasion. Dr. George Aagaard served as master of ceremonies and introduced the several participants in the program.

THE UNIVERSITY'S COLLEGE OF MEDICAL SCIENCES

HAROLD S. DIEHL, M.D., Dean

Never before have we had such an occasion as this at the University of Minnesota. We have had other medical faculty dinners, and on rare occasions the medical faculty has expressed itself concerning its dean. But never before has our Medical School or our College of Medical Sciences been privileged to recognize the distinguished achievements of certain of our graduates. That, Ladies and Gentlemen, is the high point of our evening. But before we get to that we have some other things to attend to that I hope will be of interest.

Possibly to our guests a word of explanation concerning the College of Medical Sciences would be helpful. The Medical School has been an educational and administrative unit in the University for more than half a century. In recent years, however, the activities of this unit have expanded so greatly that the designation Medical School did not seem an adequately descriptive title. Consequently, President Morrill and I recommended to the Regents that this unit be rechristened the College of Medical Sciences. This College is now an administrative unit that includes the Medical School, the University Hospitals, the School of Nursing, the School of Public Health, the Courses in Medical and X-ray Technology, the Course in Physical Therapy, the Course in Occupational Therapy and the Department of Continuation Medical Education.

The meeting this evening is a dinner of the faculty of this College of Medical Sciences. And the first item on our program is my report on some of the major developments, activities, achievements and problems of this unit.

The Medical School

First, for a brief report on the Medical School. For a good medical school or a good school of any type for that matter, one needs a strong and active faculty, an able student body, a sound educational program and adequate facilities and support. I feel that we have such a faculty in each of the units of this College. Tangible evidence of this is the national and international recognition constantly accorded members of our staff. I wish that I had time to tell you of the important lectureships, consultantships, offices in professional and scientific societies, and prizes and awards received by members of our faculty. Unfortunately, time is too short to permit of this.

In the past year we have lost or are about to lose some faculty members whose places it will be hard to fill. Among these are Dr. Clarence Dennis, who left us to become professor and head of the department of surgery of the State University of New York College of Medicine in New York City; Dr. Arthur Kirschbaum, who resigned to become professor and head of the department of anatomy at the University of Illinois; Dr. William Cromartie, who is leaving us to become director of laboratories in the new University Hospital at the University of North Carolina, and Dr. George Aagaard, who on January 1 will take over the deanship of the Southwestern Medical School of the University of Texas in Dallas, Texas.

We are honored that members of our staff are selected for positions of such importance at other institutions, and their leaving creates opportunities for the advancement and further development of other young men here. On the other hand, the departures of such intimate friends and valued members of our group leave voids and heartaches that are slow in healing.

As to our students: we have exactly five hundred undergraduate medical students this year. This is the first time since World War II that all classes have been completely filled. Applications for admission continue to be several times the number of places available. This does not mean, however, that we are rejecting large numbers of well-qualified applicants. On the contrary, even this year the last students selected by the Admissions Committee were accepted without great enthusiasm. They, as well as a good many others, have met our minimum entrance requirements, but they do not give great promise as medical students.

Our freshman class numbers 126, which is about twenty-six more than we should accept with our present staff, facilities, and budget. However, the current need for physicians and the large number of veterans of World War II still applying for admission caused us to stretch the number of admissions beyond the optimum number. In fact, the Administrative Committee of the Medical School, feeling that the need for physicians in connection with the national defense effort is of very real urgency and importance, indicated its willingness, if the necessary funds are provided, to adopt for a limited period of time an accelerated curriculum such as we conducted during World War II. Under this program an extra class can be graduated each three years. However, neither the state nor the federal government has provided the funds to cover the additional costs of such a program, so nothing further has been done about it.

A major change in the curriculum of our Medical School was made several years ago when premedical requirements were modified to provide a broader and more liberal general education and the medical course proper was extended to include in the school year for freshmen, sophomore and junior students, the first six weeks of the usual summer vacation. At the same time, the number of hours of formal instruction in several departments were reduced. This change was made to permit the incorporation of certain new materials in the medical curriculum and to give the students more time for study and independent reading and work.

A further though relatively minor change in the curriculum was made effective this year. This provides for the elimination of all lectures and formal classes for junior students except during the first hour in the morning, that is 8 to 9 o'clock. Under this program the students will devote the entire day, except for this hour, to clerkship work and to the conferences, reading and studying pertinent thereto. Our alumni will recognize this as quite a change from the days that we spent taking notes in lecture halls from morning to night throughout the junior year. The current plan places upon the student a much greater responsibility for his own education and requires a much larger teaching staff for intimate supervision and clinical instruction, but we are convinced that the results are far better than those obtained under the old system.

Graduate Medical Education

In addition to undergraduate medical teaching our medical school carries a major program of graduate medical education. This includes advanced training both in the basic medical sciences and the various clinical specialties. During the past year more than 500 graduate students devoted full time to these various programs. This number together with the approximately 500 fellows in the Mayo Foundation of our Graduate School means that the University of Minnesota has the largest graduate training program in medicine of any university in this country—that means of any university in the world.

The clinical training of these graduate students is being carried on primarily at the University Hospitals, the Minneapolis General Hospital, the Minneapolis Veterans' Hospital and Ancker Hospital of Saint Paul, all excellent teaching hospitals. In addition affiliations for graduate training have been operating at Miller Hospital, Saint Joseph's Hospital, the Children's Hospital and Gillette Hospital in Saint Paul and with Northwestern Hospital, Saint Barnabas Hospital, the Shrine Hospital, the Kenny Institute and Glen Lake Sanatorium in Minneapolis.

This advanced training of carefully selected graduate students, some of whom go on to careers in medical teaching and research, is an important contribution to the forward progress of medicine in our state and nation.

Continuation Medical Education

Another activity of the Medical School which has come to gain a position of major importance is our program of Continuation Medical Education. This program was effectively pioneered by Dr. William O'Brien and has been splendidly developed during the past four years by Dr. George Aagaard. During the past year 24 courses for physicians, mostly of three days' duration, were offered at the Center for Continuation Study on the campus, and thirteen courses were arranged in various communities throughout the State. A total of 1909 physicians attended these courses. In addition, 1,621 individuals attended twenty-one similar courses offered by other divisions of the College of Medical Sciences. Altogether, these programs make an important contribution to better medical care and other health services in this area. Our big problem for the future is to find a successor who can carry forward the work of this department which Dr. O'Brien and Dr. Aagaard have so effectively developed.

The School of Nursing

The School of Nursing, like the Medical School, offers an advanced as well as basic instructional program. In fact, a major responsibility of a University School of Nursing is to prepare selected young women for positions of leadership in Nursing Education and Nursing Service.

At the University of Minnesota the basic nursing course was revised several years ago to make it possible for young women to obtain a Bachelor of Science degree in nursing in four calendar years instead of five years as previously. For the first two years of this program enrollment in the first clinical year averaged less than twenty students per class. Last fall, enrollment in the first clinical year increased to forty-seven, and this year we have seventy-two students in this class. We are encouraged by this increase because we are convinced that this program is sound, and certainly there is urgent need for more well qualified nurses. Personally, I look forward to the time when we will have more applicants than we can accept and will be selecting nursing students much as we now select medical students.

Advanced or postgraduate programs are offered in the fields of nursing education and the various clinical specialties of nursing, such as surgical nursing, operating-room nursing, psychiatric nursing, obstetrical nursing, etc. Last year approximately 150 nurses were enrolled in these various postgraduate programs. With the increase in the numbers of auxiliary nursing personnel in hospitals, the training of competent nursing supervisors and administrators becomes of increasing importance.

In the area of practical nursing, two programs have been successfully tried—one, a four-quarter program in practical nursing, and the other a six-quarter program in home management and practical nursing. The progress which these programs are making is encouraging.

In connection with nursing, I must take time to mention the heroic rescue work that Dr. Cowling did this past summer for the graduate nursing program. This program has been supported for the past five years by grants from the Kellogg Foundation. Unfortunately, the end of this support came last June when the University had no funds for new positions. Then our good friend, Dr. Cowling, went to several individuals and groups in Minneapolis, St. Paul and Duluth and obtained in excess of $20,000 to support this program during the current year. We are deeply appreciative of this support because it would have been nothing short of a calamity to discontinue this program at a time of such urgency.

One other comment about the School of Nursing: that is, that the Kellogg Foundation has just given the University a 5-year grant totaling approximately $100,000 to develop a program in Nursing Service Administration. This grant is further evidence of the high regard in which our School of Nursing is held by people whose business it is to know the fields of Nursing Education and Nursing Service.

School of Public Health

Our School of Public Health is truly an international settlement. Of its 250 full-time students, little less than half are from the State of Minnesota. The others are drawn from thirty-four other states and nineteen foreign countries. This is very clear evidence that this school has an international as well as a national reputation.

The School of Public Health offers programs of instruction and training for medical officers of health, for public health engineers, for public health nurses, for public health educators and for hospital administrators.

This youngest of our schools in the College of Medical Sciences is doing a job of which we are truly proud.

Medical Technology

Our four-year Course in Medical Technology continues to give the best of training to the fifty or sixty able young women who each year select this important field of medical service. All of the graduates of this course have multiple and attractive opportunities for employment before graduation. In fact, the demand for our graduates so far exceeds the supply that we wish we might have 25 to 30 more students per class.

Physical Therapy and Occupational Therapy

Our courses for physical therapists and for occupational therapists were inaugurated during World War II to help meet a growing national need. Both courses are four years in length and lead to a Bachelor of Science degree. Current facilities for training necessitate a limit of approximately twenty-four students per class in physical therapy and twenty-four students per class in occupational therapy. Applicants for both programs exceed the places available. However, in spite of most inadequate facilities our faculties in both of these courses are conducting splendid programs. When we get the new Mayo Memorial, the situation for these units will be materially changed, for we will devote two floors of the tower portion of this building to a physical medicine and rehabilitation center.

Medical Research

Next a few words as to research. Today, I think, everyone accepts the advancement of knowledge as a major responsibility of a true university. In the area of research the members of the faculties of our College of Medical Sciences are exceedingly active and are achieving results that are bringing distinction to our university and to our state. In spite of this, there is much misunderstanding concerning the relation of medical teaching and medical service to research.

I well remember when I was a freshman or medical student that we were amused by the information that one of our instructors had done the research for his Ph.D. degree on "The Occurrence of Conjugated Benzoic Acids in the Urine of Sand Sharks." Whether that research had any importance I still do not know, but I do know that an investigator can develop interest in and obtain scientific training and insight from studies that seem as bizarre as the research interests of our former instructor.

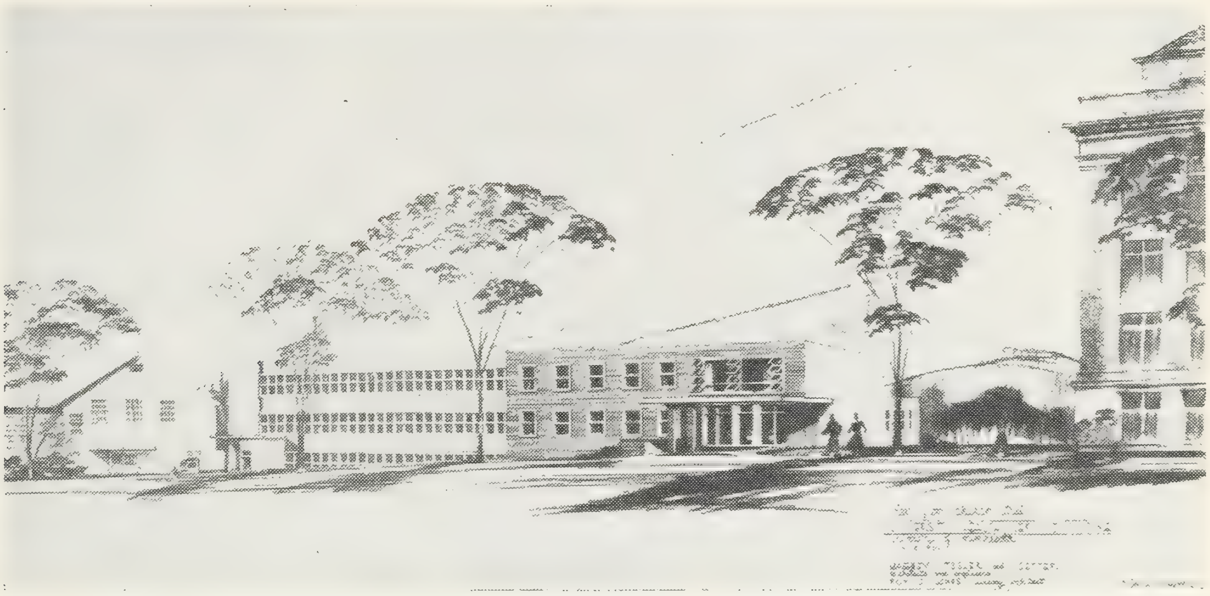

Fig. 1. Architect's drawing of the newly completed University Health Service Building.

The other day a freshman medical student said to me that he had heard from some doctor that the medical school of the University of Minnesota is a research school and that if one wants a good preparation for medical practice, he should go elsewhere. What a distressing lack of understanding such statements indicate!

Research is the spirit of inquiry put to work; and how bankrupt is a medical education that does not imbue the student with this spirit and give him a sound scientific basis upon which to keep building professionally throughout life. To learn the facts and the techniques of present-day medical diagnosis and treatment is most inadequate.

I like Charles Kettering's explanation of research. "Research," he said, "is a high-hat word that scares a lot of people. It needn't. It's rather simple. Essentially, it is nothing but a state of mind—a friendly, welcoming attitude toward change. Going out to look for change instead of waiting for it to come. Research, for practical men, is an effort to do things better and not be caught asleep at the switch. The research state of mind can apply to anything: personal affairs or any kind of business, big or little. It is the problem-solving mind as contrasted to the let-well-enough-alone mind. It is a composer-mind instead of the fiddler-mind. It is the 'tomorrow'-mind instead of the 'yesterday'-mind."

So I am proud of the research activities and achievements of the members of our faculty. I wish that time permitted me to enumerate the research programs and projects under way. They are concerned with practically every aspect of the basic sciences and of clinical medicine.

Some idea of the extent of our research activities is conveyed by the fact that last year the College of Medical Science received more than $1,250,000 from sources other than the university budget for the support of medical research. The fields of research supported by these funds are many and diverse; although our major programs of research are in the fields of cancer and cardiovascular diseases.

The sources of these funds were the Minnesota State Legislature, the Minnesota Division of the American Cancer Society, the Minnesota Society for Crippled Children and Disabled Adults, the National Institutes of Health of the U. S. Public Health Service, the U. S. Army, the U. S. Navy, the Atomic Energy Commission, the Veterans Administration, the National Research Council, the National Foundation for Infantile Paralysis, the American Cancer Society, the Allergy Foundation, the Nutrition Foundation, the Research Foundation, the Harriet Beecher Fund, other private foundations, the National Academy of Sciences, the Life Insurance Research Fund, pharmaceutical and other business corporations, finally and of very real importance, contributions by individuals.

In summary, $75,000 of the total came from the Minnesota Legislature, $862,000 from the federal government, and $384,000 from private sources. I might add that these totals do not include several endowed or privately supported research professorships, such as the George Chase Christian Professorship of Cancer-Biology, the American Legion Research Professorship in Rheumatic Fever and Heart Diseases in Children, the William A. O'Brien Professorship of the Minnesota branch of the American Cancer Society, the Pardee Cancer Research Professorship, the Mayo Professorship of Public Health. Nor do they include the capital research funds such as the Silas B. McClure bequest for half a million dollars for medical research recently received, nor the George C. Dittman bequest of approximately $400,000 for teaching and research in ophthalmology and otolaryngology. These totals also do not include the special fellowships and scholarships for selected graduate students supported from sources other than the University of Minnesota, which during the past year had a value in excess of a quarter of a million dollars.

I mention the amount of these research grants primarily to give some indication of the extent of the medical research in progress at the University of Minnesota, but the number and the amount of these grants has another implication, that is, since most of these grants were awarded by nationally chosen experts in their respective fields, the number and total of them is objective evidence of the high esteem in which the research workers and the research work at this institution are held. Meeting with these national groups from time to time I am proud and honored to represent the University of Minnesota.

Teaching and Research Facilities

Now a few words concerning our facilities. These facilities are in part on the campus and in part in affiliated hospitals, such as the Minneapolis General Hospital, the Minneapolis Veterans' Hospital, and Ancker Hospital of St. Paul. These are excellent institutions and we are exceedingly fortunate that we have them available and receive from them the splendid cooperation that exists at the present time.

On the campus we have long had a good Medical School plant and a fine University Hospital, but in recent years both of them have become very inadequate for the activities which go on in them. For a considerable number of years we have been striving to improve these facilities and I am pleased to report that finally we are getting some tangible results. During the past year two new buildings were completed and occupied. These are the Student Health Service and the Variety Club Heart Hospital.

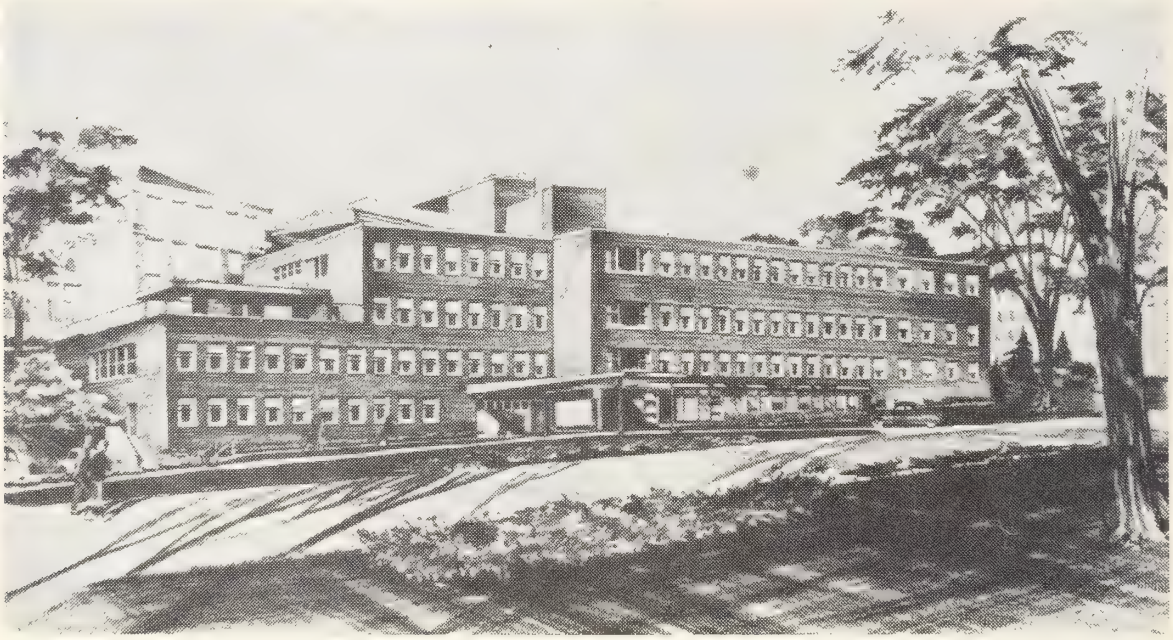

Fig. 2. Architect's drawing of the newly completed Variety Club Heart Hospital.

The Student Health Service

The Student Health Service is not administratively responsible to the College of Medical Sciences, but the Health Service and the Medical School function so intimately together that we feel that they belong to our family. The new Health Service Building (Fig. 1) is a beautiful and modern health center and out-patient clinic. Students who are bed patients will continue to be cared for on the fourth and fifth floors of the old Health Service Building. The first two floors of this same building have been available to the University Hospital and are being utilized for the extension of our out-patient clinics. The top floor of the old Health Service has been remodeled for offices, research laboratories, and labor and delivery rooms for the Department of Obstetrics.

The Variety Club Heart Hospital

This hospital, which only recently was placed in complete operation, is a splendid unit for teaching, research and for the care of patients with cardio-vascular diseases (Fig. 2). The west half of the first floor of this building is devoted to an out-patient clinic and the east half to the administrative offices, the x-ray department and research laboratories concerned with the study of congenital heart disease. The second floor contains forty beds for adult patients. The third floor is the children's unit of forty beds, while the fourth floor is devoted entirely to research laboratories. Approximately one-half of this floor is utilized for the study of infectious types of heart disease such as rheumatic fever, while the other half is utilized for the study of degenerative types of cardiovascular disease, such as coronary occlusion, arteriosclerosis, and hypertension.

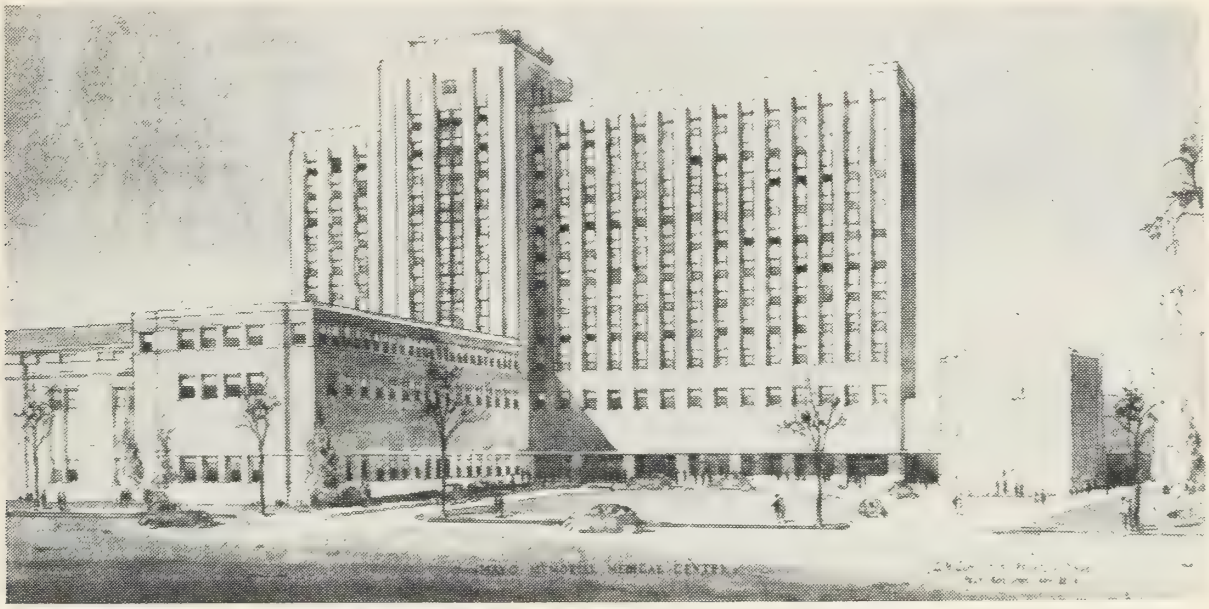

Fig. 3. Architect's drawing of the Mayo Memorial Medical Center of fourteen stories now under construction.

If there are any of you who have not seen this building, I would urge you to take time to go through it.

The Mayo Memorial

The building known as the Mayo Memorial was first proposed more than ten years ago. Its purpose was to provide improved and expanded facilities for the Medical School, the University Hospital, and other units of the College of Medical Sciences. Eighteen months ago we had twelve and a quarter million dollars and plans partially completed for a twenty-two story building for this development. Contracts for the excavation and footings and for underground services were awarded before the outbreak of hostilities in Korea and this work was completed last January. Unfortunately, the 25 per cent increase in building costs during the last six months of 1950 caused the bids for the construction of the building, received last February, to exceed by approximately three and a half million dollars the money available. Modifications in specifications, such as the substitution of a large amount of baked enamel for stainless steel, the substitution of wood windows for aluminum windows, the elimination of a great deal of tiling, et cetera, reduced the deficit to two-and-a-half-million dollars. The committee of Founders, of which Dr. Donald J. Cowling is chairman, requested a deficiency appropriation in this amount from the Legislature. And until the last evening of the legislative session, we were hopeful that this appropriation would be granted. However, as you know, the Legislature adjourned without making any appropriation for this project. That failure necessitated a major revision and curtailment of our plans.

Bids on these new plans and specifications were received about a month ago and fortunately are within available funds. The major change involved in our plans was in the reduction of the tower portion of the building from twenty-two to fourteen stories. In addition, eliminations and substitutions of less expensive materials were made wherever possible. Contracts on this building have been awarded by the Regents, and I am glad to say that work is again under way with a scheduled completion date of January, 1954.

It has been a depressing sight that I have had for the last nine months, looking out of my window into the chasm of the excavation with nothing going on. During this period, as you know, there have been various suggestions for the use of this hole, such as filling it with water, stocking it with fish and calling it "Diehl's Lake."

The perspective of the curtailed fourteen-story building is shown in Figure 3. Fortunately, the bids permit us to include the auditorium and classroom unit which is urgently needed. The auditorium will seat approximately 600 persons, and beneath the auditorium will be two classrooms which will contain something over 150 seats each. We were able also to include a two-level underground garage which will provide parking facilities for 325 cars. The finishing of the fourteenth floor of the tower which will provide offices and research laboratories for the Department of Pediatrics is not included in the construction contract. We are very hopeful, however, that we shall be able to finish this out of the contingency fund.

The eight floors eliminated from the tower were the two floors for pathology, two floors for cancer biology, one floor for biophysical research, one floor for histo-cyto-chemical research, a half floor for the School of Public Health and a half floor for offices and conference rooms for the Medical School and the department for Continuation Medical Education and a floor for the Medical-Biological Library. In fact, the library floor was the equivalent of almost two other floors in height.

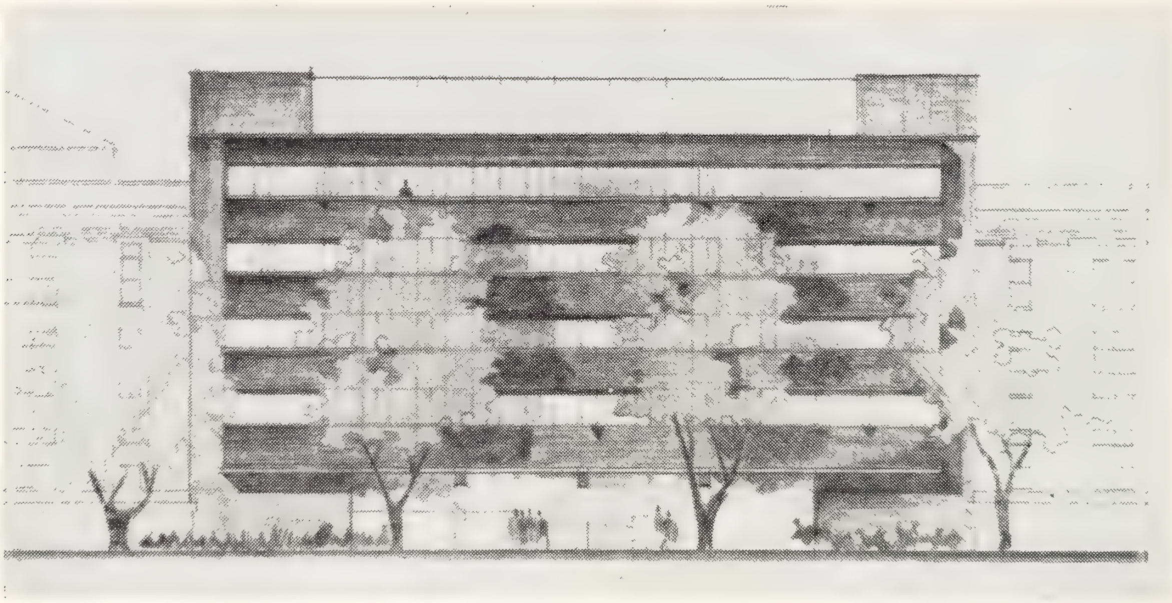

Fig. 4. Proposed building for Cancer and Heart Research to join Millard Hall and the Anatomy Building.

I regret that we shall be unable to give the Department of Pathology the new teaching and research laboratories which were planned for the new building and simultaneously return to the Department of Anatomy the Anatomy Building which it occupied exclusively from the time of its construction in 1912 until 1920. We believe, however, when this building is adequately remodeled and modernized, as proposed in the University's building program, that the Departments of Pathology and Anatomy can continue to function reasonably satisfactorily in this building.

The four floors for research—that is the two floors for cancer biology, the floor for biophysics and the floor for histo-cyto-chemistry—will be housed in a new unit to be constructed along Washington Avenue, adjoining Millard Hall and the Anatomy Building (Fig. 4). The funds for the construction of these floors in the Mayo Memorial were provided by special grants, and we were able to secure authorization to transfer these funds to this new building, the construction of which will be much less expensive than the tower would have been. The plans for this building are being prepared, and we believe that the building will be completed before the Mayo Memorial.

This program, as you doubtless have noted, leaves out completely the Medical Biological Library. Actually, before the plans for the Mayo Memorial crystalized, the faculty voted that provision for the medical-biological library on the medical campus was a top priority need for the Medical School. As it appeared then that there might be federal funds to aid public building following World War II, we had prepared plans and specifications for a medical biological library to be located in the vacant corner between the Anatomy Building and the Medical Sciences Building. Actually, this location for the library, since it will serve the College of Dentistry and the departments of zoology and botany as well as the Medical School, is in some regards preferable to the tower location.

The architectural perspective of this new building, prepared about eight years ago, is shown in Figure 5. Incidentally, this building also provides for a pathological museum, which was to have been housed in one of the floors of the department of pathology in the Mayo Memorial tower building.

As plans and specifications for this building are all completed it is our hope that it will be possible to obtain funds for its construction within the next couple of years. If this can be done it should be possible to complete this important unit not long after completion of the Mayo Memorial.

Future Plans and Problems

This completes my report for the College of Medical Sciences but, lest everyone think the picture is all rosy, I should mention some of our problems. These problems, as you doubtless have guessed, are mostly financial.

The most serious problem of all is basic support. Over the years, the Legislature has done very well by the University, but inflation and rising costs are giving rise to serious problems both as to staff salaries and to operating expenses. There frequently is not a great deal of difference budget-wise between a first-class institution and a mediocre one. And we just must improve salaries if we are to attract and retain the type of faculty which makes Minnesota the quality of institution that it is. We also must increase budgets for other operating expenses.

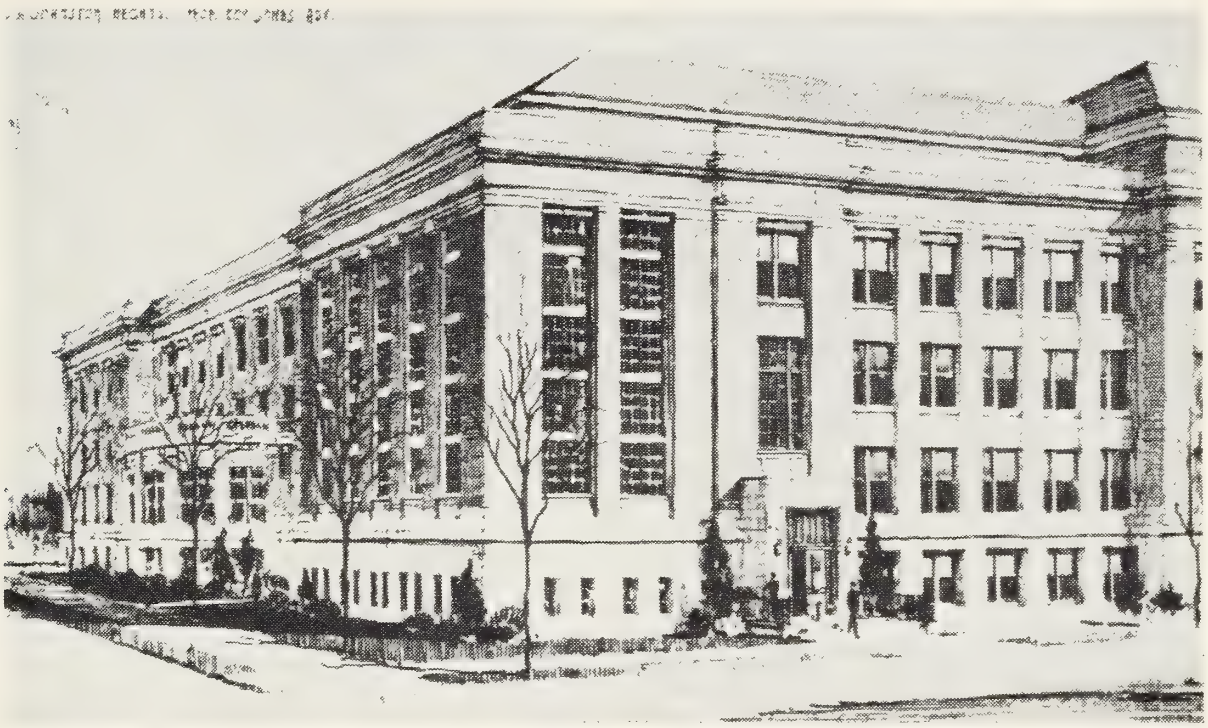

Fig. 5. Architect's drawing of the proposed Medical Biological Library.

Another problem ahead is that, in order to provide funds for the construction of the Mayo Memorial, it was necessary to reduce funds for equipment and for the remodeling of the University Hospitals way below what will be needed for effective operation of these units. It is my hope that while the Mayo Memorial is under construction, we shall be able to obtain special gifts for scientific and other types of equipment needed for this unit. The securing of funds for other than military purposes is not easy these days, but it can be done and I am sure that we can look forward with optimism to the years ahead—years which I am sure will produce achievements in which we and our University can take continuing pride and satisfaction.

PRESENTATION OF ACHIEVEMENT AWARDS

J. L. MORRILL

President, University of Minnesota

Too often there is a kind of short-circuit in communication when the stay-at-home patriot stands up to praise the front-line soldier.

The patriot is full of generous sentiments, but he fails to express them in a way that means anything to the soldier who still sees and hears the sights and sounds of battle. One writer has put it this way: To a fighting man, words like courage, glory, valor and heroism sound hollow and meaningless beside the concrete names of battlefields and towns, the numbers of regiments, roads and bridges.

This inability to say the right and proper thing troubles me in saluting those to whom we would pay tribute tonight—the alumni and staff and faculty of our College of Medical Sciences.

Engraved in your minds and memory must be countless victories in the struggle with death and disease and human disheartenment. Your triumphs are recorded in the special language of your profession: in case histories, in learned journals, technical volumes and laboratory reports. Your work becomes widely known only when you have concluded the patient work of investigation, experiment and compilation and emerge into the light of publicity with some gift of life to offer.

But what merits highest praise is the day-to-day regimen of scientific discipline which you impose upon yourselves. All this we, your patients and laymen, cannot share or really understand. We are handicapped in expressing our respect and appreciation. I can only declare the pride and gratitude which the University, the state, and the nation feel in the great work which you, and your predecessors, have accomplished and continue to accomplish.

Perhaps the reward most meaningful to a scientist is simply to give him a place to carry on his work; to place at his disposal the means and opportunity which will allow him to make his best effort. This is the kind of tribute which best reveals true understanding of what he is trying to do.

Through the years, the medical scientists of the University of Minnesota have earned many such tributes. Our medical facilities have been increasingly expanded by grants, by gifts and memorials from the State, from Federal agencies, from private organizations and from generous individuals.

The latest additions—the Mayo Memorial Medical Center and the Variety Club Heart Hospital—are clear-cut expressions of widespread faith and confidence in the University of Minnesota's community of medical men and women.

These new buildings were made possible by the contributions of many loyal partisans in the cause of human welfare. Almost every agency of a democratic society has participated in their creation. The Mayo Memorial is founded on appropriations from a generous state legislature; additional funds have come from Federal agencies—through the Hill-Burton Act, the National Cancer Institute, and the National Heart Institute of the U. S. Public Health Service; from the American and Minnesota Cancer Societies and from thousands of individual donors.

Most of you know the moving story of the Variety Club Heart Hospital at the University of Minnesota; how it was sponsored by a colorful association of showmen; how organizations and people from all walks of life joined in the work to bring it to fulfillment. The Heart Hospital is now in full operation. It is splendid with vivid colors and flooded with daylight—in harmony with the bright promise it holds for those who come there under a cloud. All of this only serves to illustrate a fact which must be a source of great pride. It is this: Minnesota Medicine has attained more than scientific stature; it has attained human stature, the goal of all your endeavor.

This faith in our College of Medical Sciences is promoted, not only by what is done here in the University Hospitals and laboratories, but through the influence and achievements of our distinguished alumni all over the world. Tonight, we honor some of them. Some are noted for their leadership in research and treatment. Some are outstanding for their work in some phase of public health.

This is a taken-for-granted term today—public health; and we tend to accept as commonplace the significance of the term. But there is nothing at all commonplace, nothing that can be taken for granted, in the idea which is implicit in the term "public health." Actually, public health is a relatively new social and humane concept. Its province is to secure a fundamental right of mankind—*the right to physical and mental well-being.* Indeed, this right is prerequisite to the full enjoyment of all of our other rights.

Rudolf Virchow, the great German pathologist of the 19th century, who was also an astute diagnostician of social ills, made the strange statement that "Medicine is a social science, and politics is nothing else than medicine on a large scale."

In these broad terms, we see the relationship of medicine to society. It is this: In pursuing its own proper ends, medicine pursues the ends of social and human welfare. Dr. Henry E. Sigerest of Johns Hopkins said the same thing more practically in recommending a public health program for adoption by all the civilized countries in the world. He advocated:

> "Education for all, including health education; the best possible working and living conditions; the best possible means of rest and recreation; a system of health institutions and medical personnel, available to all, responsible for the people's health, ready and able to advise and help them in the maintenance of health and in its restoration when prevention has broken down; centers of medical research and training."

This is the challenge confronting those who prosecute research and who strive to spread its benefits through professional service and programs of public health. Societal response to this challenge is plainly discerned in this country and in other areas of the world.

It is one of the purposes of the "Outstanding Achievement Awards" to express the University's appreciation to the alumni of the College of Medical Sciences who have been instrumental in making such progress possible.

Many of the recipients have already been honored in other places and in other ways. Their work is well known to most members of this audience.

Recognition of scientific attainment, indeed, is not so long in coming today as at one time it was. In the seventeenth century Thomas Hobbes wrote of his friend, Dr. William Harvey: "He is the only man, perhaps, that ever lived to see his own doctrine established in his lifetime." The doctrine, of course, was Harvey's new teaching on the circulation of the blood.

Times have changed. Nowadays, it is difficult to keep abreast of the medical attainments which merit praise. But we can *begin* to catch up on our own obligations, at least, this very moment. It is now my happy privilege to present the awards through which the University endeavors to acknowledge, with admiring respect and appreciation, some of its outstanding alumni in Medicine and Public Health.

In asking the first recipient to come forward, I shall read the full text of the certificate—reading thereafter simply the individual citations.

The Regents of the University of Minnesota
As a Token of High Esteem and
In Recognition of Noted Professional Attainment by

FRED L. ADAIR

Distinguished Graduate of the University of Minnesota
Emeritus Professor of Obstetrics and Gynecology of the University of Chicago
Nationally Honored for His Work in Reducing Maternal Mortality
Deem Him to be Worthy of Special Commendation for Outstanding Achievement
Conferred on October Eighth, Nineteen Hundred and Fifty-one

* * *

FRANK E. BURCH

Distinguished Graduate of the University of Minnesota
Emeritus Professor of Ophthalmology in its College of Medical Sciences
Pioneer in the Movement for the Prevention of Blindness.

* * *

EARL R. CARLSON

Distinguished Graduate of the University of Minnesota
Internationally Known Neurologist, Writer, and Lecturer
Unstinting Worker for Advancement in the Study and Treatment of Cerebral Palsy.

* * *

ALBERT J. CHESLEY

Distinguished Graduate of the University of Minnesota
Executive Officer of the Minnesota State Department of Health
Loyal Supporter of Public Health Education in the University
Elder Public Health Statesman of the Nation.

* * *

ARILD E. HANSEN

Distinguished Graduate of the University of Minnesota
Professor and Chairman of the Department of Pediatrics and
Director of the Child Health Program of the University of Texas
Nationally Respected Authority on Rheumatic Fever.

* * *

ALMA C. HAUPT

Distinguished Graduate of the University of Minnesota
Director of the Nursing Division of the Metropolitan Life Insurance Company
Eminent Contributor to the Health of a National at War and at Work.

* * *

HERMAN E. HILLEBOE

Distinguished Graduate of the University of Minnesota
Commissioner of Health, the State of New York
Outstanding Public Health Administrator
Significant Contributor to Tuberculosis Control.

PEARL L. McIVER

Distinguished Graduate of the University of Minnesota
Chief of the Division of Public Health Nursing of the United States Public Health Service
Celebrated Nurse and Pioneer in the Federal Health Services.

* * *

JAMES E. PERKINS

Distinguished Graduate of the University of Minnesota
Managing Director of the National Tuberculosis Association
Noted Epidemiologist and Administrator
Valued Adviser in International Public Health Planning.

* * *

EDITH L. POTTER

Distinguished Graduate of the University of Minnesota
Professor of Pathology of the University of Chicago
Renowned for Research in Diseases of the Newborn and for Investigation in the Rh Problem.

* * *

WILLIAM P. SHEPARD

Distinguished Graduate of the University of Minnesota
Vice President of the Metropolitan Life Insurance Company
President of the American Public Health Association
Wise Administrator, Teacher, and Leader.

* * *

ALBERT M. SNELL

Distinguished Graduate of the University of Minnesota
Senior Internist, Palo Alto Clinic, Internationally Acclaimed for His Research in Gastro-enterology
Inspiring Teacher of Internal Medicine.

* * *

EDWARD L. TUOHY

Distinguished Graduate of the University of Minnesota
Chief of Medicine of the Duluth Clinic
Steadfast Exemplar of the Highest Standards in Medical Practice
Crusader for Study and Research in Geriatrics.

Unable to be present but approved for Outstanding Achievement Awards by the Regents of the University were:

RAYMOND B. ALLEN

President, University of Washington, Seattle, Washington.

GEORGE O. BURR

Head of the Department of Physiology and Biochemistry, Experiment Station, Hawaiian Sugar Planters Association, Honolulu, Hawaii.

OLAF J. HAGEN

Physician, Fargo, North Dakota, and Former Member Board of Regents, University of Minnesota.

C. J. VAN SLYKE

Director, National Heart Institute, United States Public Health Service, Washington, D. C.

PRESENTATION OF PORTRAIT OF DEAN DIEHL

E. T. BELL, M.D.

Emeritus Professor of Pathology

This occasion is in no sense a farewell party to the Dean, but rather an occasion for rejoicing. Sixty years is not advanced age. I wish I were sixty again.

Perhaps I was chosen to make this presentation because I am one of the few among us who can remember when Harold was a boy. It may have been because I can sing his praises without fear of being accused of currying favor. My present salary cannot be adjusted up or down. I would like to believe that I was given this honor because I have known Harold and have been closely associated with him throughout his academic life.

He began his graduate career as a pathologist—a circumstance which to me indicates an early maturity of judgment. He directed the Student Health Service from 1921 until 1935, and under his leadership the Health Service gained the confidence of the students and the community.

Since 1935, he has been Dean of Medical Sciences and under his guidance our Medical School has become one of the best in our country, both in teaching and research. He believes in good teaching and he also does his best to promote research. He has welded us together as a friendly co-operative group. It is a joy to all of us to congratulate him on his long successful career.

I have said some other things about our Dean which are printed on your programs. Some of my discourse was deleted to make room for his picture which you see on the program. But after viewing this alleged likeness of the Dean, I think it would have been better to have had more remarks and less picture.

I am afraid, Mr. Morrill, that you regard this present which we are about to give you somewhat of the nature of a husband's gift of a box of cigars to his wife. We hope you will give it back to us. If you should do so, we shall hang the portrait in some appropriate place in the New Mayo Memorial Building. I should not like to put it among the Dean's bewhiskered predecessors who now adorn the Faculty Room in Millard Hall. Perhaps we shall start a new series of Super Deans who do not possess hirsute adornments.

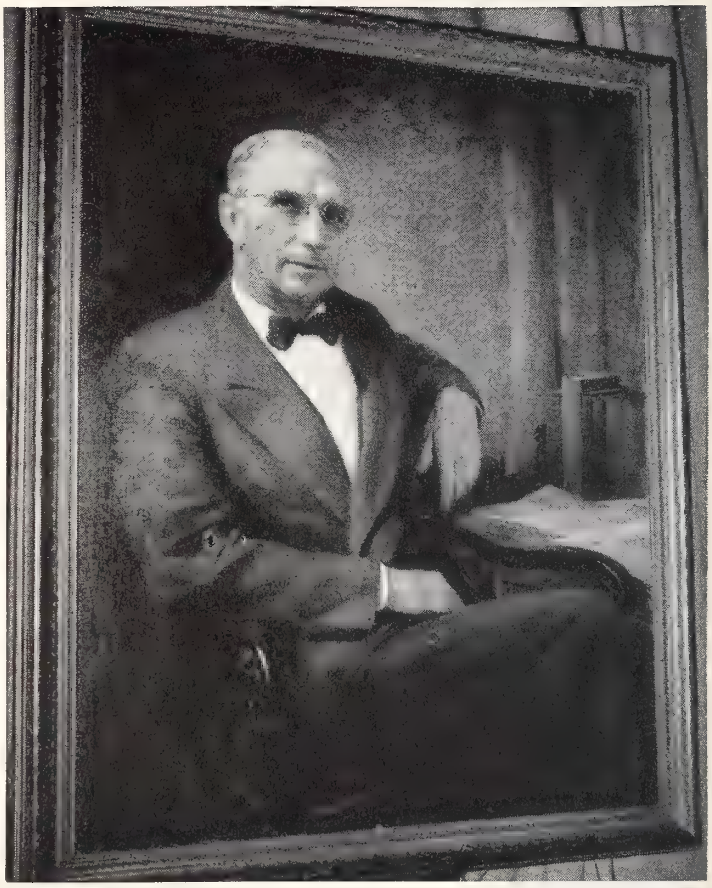

Fig. 6. Portrait of Dean Harold S. Diehl presented to the University of Minnesota by the Medical Faculty, October 8, 1951.

If any difficulty should develop about finding a proper place for the portrait, there will always be room for it in the Bell Museum. I rather favor this idea. Some people regard Pathological Exhibits as somewhat depressing, and a portrait might liven up the exhibits.

Mr. Morrill, it is now my privilege on behalf of the Medical Faculty to present to the University a portrait of Dean Diehl. It is a tribute to the best Medical Dean Minnesota has ever had, and even more importantly it is a token to Harold and Julia of our deep affection.

REMARKS IN ACCEPTANCE OF PORTRAIT

President J. L. Morrill: Dr. Bell, Dean Diehl, ladies and gentlemen, I am happy, indeed, to accept this splendid portrait in behalf of the University.

Surely, this expression of respect and regard on the part of your colleagues must be heartening and rewarding to you, Dean Diehl, and to Mrs. Diehl, as it deserves to be.

The integrity and prestige of our University, as all of us know, are the sum of the productiveness and the distinction of the individual staff members—inspired and assisted by far-sighted and energetic leadership. Dean Diehl, indeed, has brought leadership of the highest order to the College of Medical Sciences and thereby to the University of Minnesota.

On behalf of the Regents, I am delighted to receive, Dean Diehl, from your colleagues, this manifest and living memorial of your devotion and achievement.

Dean Harold S. Diehl: I am most deeply touched by the honor that you have paid me here this evening. But before speaking of that, I cannot resist telling you of an incident of which the unveiling of my portrait reminded me. This occurred in Washington at the unveiling of a marble bust of Justice Holmes, done by a famous sculptor. After the ceremonies, an attractive young woman came up to Justice Holmes and said that she had always been an admirer of his and that she had travelled all the way from California to be present at the unveiling of his bust. Justice Holmes replied that he was flattered, indeed, and that he would be glad to return the compliment at any time.

One other thought in a light vein is that it is a well-established University custom that portraits of deans are presented at the time of their retirement. This being true, if I were a person to look for ulterior motives, I might suspect that the presentation of my portrait at this time is a subtle suggestion that I might take appropriate action to conform to University custom. Actually, however, if that is the intent, you will have to be much more direct and blunt, because, like George Grim, "I Like It Here." And liking it, I hope to be around for a few more years.

Another thought, Mr. President, about this last item on the program, that is quite embarrassing to me, is that it indicates how little control I have over my faculty. We planned this meeting to make the distinguished achievement awards to our alumni, and I appointed a committee to arrange for the meeting with definite instructions as to what they were to do. The program was to end with Dr. Bell's talk, and he was to speak about the Medical School and anything else that he might wish to discuss with our distinguished guests. Then, without even consulting me, the program was changed. This, of course, is in evidence of complete disregard of administrative authority. It is a type of action that in the Navy might even be called mutiny. This, to me, is most embarrassing and may be indicative of an ominous trend. However, believing that their intentions were good and being much pleased with the end result, I shall not prefer charges against them.

Seriously though, my colleagues and friends, I am deeply appreciative of your expressions of confidence and good will, more appreciative than I can possibly put into words. With you, I am proud of the progress that our Medical School has made during my period of administration. In all honesty, however, I can take very little personal credit for this because I have had help, encouragement, and support from all sides. There was little, if anything, that I accomplished alone.

First of all, I want to acknowledge the credit that rightly belongs to Mrs. Diehl. For thirty years she has not only made a splendid home for our family but also has helped, encouraged and supported me in my work. At times, she has even needled me a bit to get things done. She has been superb, not only as a companion but also as your Dean's wife.

Also, over these years, I have had the good will, the understanding, and the support of the central university administration. President Coffman, President Ford, President Coffey and currently President Morrill, by their wise counsel, encouragement, and support, made it possible for us to move continuously forward. The same is true of Mr. Middlebrook, Mr. Willey, Mr. Lunden, and others of the central administration. It has been true also of Dean Blegen, Dr. Balfour, Dr. Victor Johnson, in connection with our graduate training program. I have had the benefit also of the interest and the support of the medical profession and of many non-medical friends throughout the state. And finally, and most important of all, I have had the constant and unfailing help, loyalty and support of the faculty and staff. With such colleagues and friends, one could not fail.

From my point of view, the sixteen years I have served as your Dean could hardly have been more pleasant and more satisfying. We have had our problems and our disappointments as well as our achievements, but the disappointments have merely served to make our achievements more gratifying and our successes more sweet.

In this life, rewards do not come in any better coin than satisfaction in one's work and the esteem and affection of one's colleagues. I frequently wonder how I was so fortunate as ever to have had the opportunities which the University of Minnesota has given me over the past thirty years.

As I said before, "I Like It Here," and I appreciate more than I can possibly express, the honor you have paid me. I assure you that in my remaining years with the University I shall spare no effort to merit the confidence and good will which you have expressed here this evening.

In conclusion, I want to express my thanks to the committee that made the plans for the portrait and for this meeting; to Mr. Nunn, who so kindly and efficiently made and carried out the arrangements for this dinner; and to my colleagues and friends who made this portrait possible. I want also to express to Mr. Edward Brewer, the artist, my congratulations on this splendid portrait and my thanks to Mrs. Brewer for her enthusiastic interest and her many helpful suggestions. I am very pleased, Mr. Brewer, that the Committee selected you as artist to do this portrait.

Finally, this has been a wonderful evening for Julia and me. We do appreciate it and thank you.

Medicine is now threatened with a philosophy, a battle if you will, which involves the very survival of our democracy, our freedom, and our way of life. The zeal of those in high places, of certain elements in industry, in labor, and in our ancillary professions to correct social inequalities by nationalizing the profession of medicine can result only in the destruction of a system of medical care which is the envy of the entire civilized world. The ultimate result can be only the production of greater injustices than existed previously and the deterioration of the quality of medical care.

Socialism and communism flourish in times of economic hardship and distress. This ideology appears as a panacea for the alleviation of temporary problems without due consideration for the long-term effects such doctrines will produce. The very essence of hope and a portent for the future lie in the revival of optimism in our reliance on the God of our fathers so beautifully expressed by that strong antagonist of atheistic communism, the Right Reverend Fulton J. Sheen, when in his Easter sermon in New York City he said, "In the providence of God, communism may be the fertilizer of a new civilization, the death that is spread over the world in the winter of its discontent to prepare the dead earth to tell its secrets in the new springtime of the spirit."—J. Stanley Kenney, M.D., Conference of Health Officers and Nurses, Lake Placid, N. Y., June 4, 1951.

Roger L. J. Kennedy, M.D.
President, Minnesota State Medical Association

President's Letter

OBJECTIVES OF THE COMING YEAR

I have often thought that the psychologic impact of the end of one year and the beginning of another, usually marking the start of new tenures for officers of groups such as the Minnesota State Medical Association, actually can create more problems than it solves.

Thus, each twelve months we have no choice but to close the books on the old year, despite the fact that some project or piece of business initiated in September or October, for example, has no logical reason for coming to an abrupt conclusion on January 1, and in fact often does not do so. Yet the tyranny of the mathematics in the calendar system requires the incoming president of the association to summon up his powers of prescience as best he can, to assay the weight and nature of coming events, and to embrace those measures which in his opinion will best serve the interests of the organization.

Such an assignment, in the face of twelve months yet to come, the import of which cannot be known by any man, is difficult indeed. There are, nonetheless, certain positive actions which can be carried out by any incoming officer, and I think they are valuable enough to be mentioned here.

First, I propose to learn as much as I can about the organizational structure of the Minnesota State Medical Association. This in itself is no simple task, for during the years we have created scientific and nonscientific committees, liaison positions and other posts or units which subserve a number of vitally useful functions, all subordinate to the business of maintaining the organization itself. It seems to me that a successful president of the association must have a thorough understanding of the duties and activities of each of the special groups I have mentioned.

Second, I shall endeavor to continue the close and cordial working relationship with the executive secretary of the association. Both the association and the public at large derive great benefits from the efficient work carried out day by day in the office of this eminently useful representative of our membership.

Third, I shall attempt to familiarize myself as extensively as possible with the twin-edged problem of ascertaining, primarily, what the health needs of the community actually are, in as many aspects as is feasible, and, next, in careful study of what methods can be used to satisfy, in equitable measure, those needs. The fact that this problem currently is being accorded, as it has been for some years, intensive study on a national scale only emphasizes the magnitude of the task, even within the confines of a state.

The fourth objective I have in mind will, in some measure, contribute to progress in solution of the problem implied in the third. That is, the planning and presentation of a scientific program which embodies the latest advances in the fields of medicine concerned, as well as current additions to knowledge in these fields, and will enable each member readily to familiarize himself with the utmost which can be done for his patient in a given case. This knowledge inevitably is reflected in better medical counsel and treatment within the community as a whole.

A factor which sometimes is forgotten is the great opportunity, within an association such as this one, for the perfecting of a sound and strong organization on the basis of the friendship and co-operative labors among the membership itself. It is a good and satisfying thing to know what ones colleague is doing, to realize that the counsel of his experience can be had at any time, and to consider that the bond of friendship within the organization actually has no limitations.

It would be a hardy man, indeed, who would maintain that all the foregoing objectives can be fulfilled within the space of a single year, but progress in the direction of any one of them would be an achievement well worth while. Without in the least wishing to expose myself to the possible charge of presumption, I nevertheless hope that the sympathy, patience and understanding of the membership, combined with the best efforts of which I am capable, will in the end provide all of us with some cause for pointing to a degree of progress in 1952.

A MILESTONE

WITH THE ADVENT of another year we pause to look back on the year that has passed and at the same time look forward to the year 1952.

The past year saw a reversal in thinking in England manifest by the return of the Conservatives under Churchill to control of the government. Socialism has not worked for a betterment of social and economic conditions in England.

The United States has been following England down the road to Socialism. To obtain a vivid picture of the true state of affairs, those who failed to hear the addresses of Senators Taft and Byrd to the AMA House of Delegates in Los Angeles in December when they were broadcast to the nation, should read both addresses in *The Journal AMA* for December 15 (p. 1576). No stronger criticisms of the road to Socialism being taken by the present administration can be imagined than these two speeches, the one by the Democratic Senator particularly. There is a growing realization very generally that the time has come to call a halt to deficit government spending and increasing taxation, if we are to avoid collapse. That the next year will be a crucial one in the history of our country seems to be very generally recognized. The same opinion is being voiced by Vogeler, the International Telephone and Telegraph representative in Hungary, who has returned to America after seventeen months in solitary confinement in Hungary. He is spending his time warning the people of this country of the danger threatening our freedom today, not only from Russian communism but from a powerful federal government which can ignore and has ignored the Constitution.

The AMA publicity campaign which, though undertaken primarily to prevent the socialization of the practice of medicine, actually spearheaded the attack on socialism in government, was successful in preventing compulsory federal sickness insurance legislation for the time being. The fight to prevent socialization of medical practice and after that socialization of all other activities has only begun. The physicians of the country may feel proud of the part they have played so far and need not feel apologetic in their espousal of our so-called capitalistic system which assures individual freedom and initiative.

During the past years, medical schools and, in fact, most of the universities not supported by government units, have been unable to stay out of the red. To meet the distressing situation, the first thought with many has been to ask for federal aid. With a federal control of university finances, would and should go a share in the administration of the universities. This increase in the power of the federal government is just what is rightly feared. And if the federal government helps out the universities, a strong argument will be presented for federal aid to high schools, grade schools and other educational activities. The American Nurses Association at present is advocating federal aid for the training of nurses. With this policy the medical profession cannot agree.

In an effort to avoid federal subsidy of the medical schools, the American Medical Education Foundation was established by the AMA House of Delegates in December, 1950, with an appropriation of $500,000 of AMA funds. An equal appropriation was made again in December, 1951. All funds raised will be funneled to a newer and larger organization known as the National Fund for Medical Education, which accepts contributions from a wider field in the hope of obviating the need for federal assistance. It is to be hoped that the year 1952 will see the successful outcome of this important undertaking.

MINNESOTA MEDICINE

FOR A GOODLY number of years, the secretaries of the state medical associations and the editors of the state journals have met in conference at AMA headquarters each year to discuss medical affairs. The two-day sessions have served to clarify medical problems and unify thinking as to public relations and policies.

For several years a meeting of presidents and officers of state medical associations has been held in advance of the annual AMA meeting each year at which a similar program was presented. Then again, the interim AMA meetings held the past three winters have been preceded by Public Relations programs similar in character. For this and possibly other reasons, the conference of secretaries and editors has been dispensed with.

In view of the fact that most of the state editors did not attend the meeting of presidents and officers of state conventions and feeling that a periodic get-together of editors is highly desirable, the AMA Trustees, at the instigation of the Advisory Committee of the State Journal Advertising Bureau, arranged for a meeting of editors alone in Chicago on November 12 and 13 last. It is the present plan to hold this meeting in Chicago biennially.

The many facets pertaining to the publication of a state medical journal received discussion. Being a professional journal its value depends largely on the content of scientific material. According to a survey reported at the meeting, clinicopathological conferences and case reports are most popular with the readers. Original articles, so-called, come next. These two departments comprise the backbone of the state journal and their quality determines the standing of the journal. It is difficult to determine how many subscribers read the editorials. That they are not read more often is doubtless the fault of the editors. That they are read to some extent becomes obvious when an opinion is expressed on some controversial subject. Editorials, however, should express opinions of the editor, rather than simply recite facts, as so many do. It is generally conceded that editors of medical journals should feel at liberty to express opinions on government policies but should refrain from taking side in partisan politics. Editors recognize that they cannot always be right and welcome attention being called to their mistakes or the expression of contrary opinions in "communications to the editor."

There is one department in a state journal which is distinctive—the personal or general interest column. All readers have an interest in what their friends and neighbors are doing. While the newsy quality of this department suffers from a necessary delay of some weeks in appearance in print, we urge county secretaries and, in fact, all our readers to submit news items about themselves or acquaintances.

We desire more original articles, so-called, and more case reports. Minnesota Medicine affords an outlet for the 3,000 or more members of the State Association to present their ideas and experiences to their fellow physicians. Submitted articles should be brief and free from superfluous wordage. Articles on clinical phases of medicine are particularly desired. For a variety of reasons, we have been receiving fewer papers for publication and would appreciate the cooperation of members in this regard.

As we enter 1952, we wish our readers a very Happy New Year and again pledge our cooperation to the officers and membership of the Association. At the same time, we request the cooperation of the membership in making Minnesota Medicine bigger and better in every way.

NEW LAW REGARDING PRESCRIPTIONS

THE NEW LAW regarding the refilling of prescriptions under the Durham-Humphrey bill passed recently by Congress is sensible and a step in the right direction. It becomes effective April 26, 1952—six months from passage.

According to the new law, drug manufacturers will be required to label a drug as dangerous, which, "because of its toxicity or other potentiality for harmful effect or the method of its use, or the collateral measures necessary to its use, is not safe for use except under the supervision of a practitioner licensed by law to administer such drug," with the label "Caution—Federal Law prohibits dispensing without prescription." The druggist will require a prescription, written or given over the telephone, for the dispensing of a drug so labeled. The druggist must keep a file of telephoned prescriptions and check them back with the prescriber to be sure of his identity.

The definition of drugs limited to prescription, as interpreted by the Food and Drug Administration, includes among others: penicillin, barbiturates, benzedrine, dexedrine, sulfa drugs, antibiotics, thyroid and male and female sex hormones.

This clarifies the drugs requiring prescriptions, as far as the druggist is concerned. He can fill or refill others over the counter without prescription. This simplifies the prompt procurement of medicine that requires a prescription which ofttimes was impossible formerly without breaking the letter of the law.

AMA PRESIDENT'S SCHEDULE

FOLLOWING is a three weeks' schedule of John W. Cline, M.D., president of the AMA, lifted from the November issue of the *Pennsylvania Medical Journal.*

September 9—Left San Francisco 7:45 a.m., and arrived in New York 8:55 p.m.

September 10—Left New York for New Haven.

September 11—Visited Yale Medical School followed by cocktail party and dinner at New Haven Lawn Club, speaking on "Problems Facing American Medicine in the Immediate Future." Returned to New York from New Haven.

September 12—Left New York 7:00 a.m., arriving in San Francisco 3:30 p.m.

September 13—Left San Francisco 8:55 a.m., and arrived in Reno, Nevada, 10:35 a.m. Presented two scientific discussions on surgical subjects at Nevada State Medical Society convention.

September 14—Spoke at Nevada Medical Society's annual dinner.

September 15—Left Reno 1:05 p.m., arriving in Los Angeles 4:35 p.m.

September 16—Left Los Angeles 2:25 p.m., arriving in St. Louis 10:30 p.m.

September 17—Attended convention of American Hospital Association; present at luncheon and spoke at dinner meeting.

We venture the opinion that this man-killing pace of flitting about the country, if maintained for the entire year of AMA presidency, will leave any man a physical and nervous wreck. Somewhere a brake should be placed on the demands made on our president.

Nowadays the AMA president is called upon to sacrifice his practice and convenience in the interest of unifying the national association and furthering public relations. Our presidents should know that their sacrifice for the good of medicine is appreciated.

KREBIOZEN

THE COMMITTEE ON RESEARCH of the Council on Pharmacy and Chemistry of the AMA on October 26, 1951, after a survey of 100 case histories of patients treated with Krebiozen, a secret cancer remedy alleged to have been discovered three years ago by Dr. Stevan Durovic, a former Yugoslavian physician, reported failure to confirm the beneficial effects claimed last March by Dr. Andrew C. Ivy, Chicago physiologist and vice president in charge of the professional schools of the University of Illinois. The drug, described as a white powder soluble in water, is alleged to have been extracted from horse serum after the horses had been inoculated with an undisclosed substance. We are not informed whether this substance was undisclosed to Dr. Ivy and he administered a therapeutic agent the nature of which was unknown to him or whether he shared with the Yugoslavian physician in keeping the nature of the remedy undisclosed.

Had there not been an established agency to pass unbiased judgment on the efficacy of this alleged cancer drug, there is no telling to what lengths Krebiozen, with its presumably reliable backing, might have been used.

DOCTORS KENDALL AND HENCH HONORED

AT A DINNER meeting held at the Coffman Memorial Union ballroom, November 29, 1951, citations by the Regents of the University of Minnesota were presented to the two members of the faculty of the postgraduate medical school, Dr. Edward C. Kendall and Dr. Philip S. Hench.

As is well known, the biochemist Dr. Kendall and the internist Dr. Hench, both of the Mayo Foundation, along with Dr. Tadeus Reichstein of Switzerland, were presented with the Nobel Prize at Stockholm on December 10, 1950.

Dr. Kendall was born in 1886 at South Norwalk, Connecticut. From Columbia University he received the degree of B.S. in 1908, M.S. in 1909 and Ph.D. in 1910. In 1914, he entered the Mayo Clinic as head of the Division of Biochemistry, which position he held until his retirement in 1951. He was already well known for his isolation of thyroxin and has received numerous prizes for his scientific contributions. These include the John Scott Prize and Premium by the city of Philadelphia in 1921; the Chandler Medal from Columbia University in 1925; and the Squibb Award for 1945 for outstanding research in endocrinology.

He has served as president of the American Society of Biochemical Chemists and of the Association for the Study of Internal Secretions. He has been awarded the honorary Doctor of Science degree from Yale University, Western Reserve University, Williams College, the National University of Ireland and Columbia University.

In 1940, Drs. Kendall and Hench shared the Albert D. Lasker Award given by the American Public Health Association and in 1950 the Passano Award for the development of Compound E (Cortisone).

In 1950, Dr. Kendall was presented with the John Phillips Memorial Medal of the American College of Physicians, the award of the American Pharmaceutical Manufacturers' Association and the annual award of the Research Corporation of New York City.

In 1951, the two Mayo scientists were presented with the Award of Merit from the Masonic Foundation for Medical Research and Human Welfare and the

$10,000 Dr. C. C. Criss Award of the Mutual Benefit Health and Accident Association of Omaha, Nebraska.

Dr. Hench was born in Pittsburgh in 1896. He received his B.A. degree from Lafayette College in 1916 and his M.D. from the University of Pittsburgh in 1920. After a year's internship at St. Francis Hospital in Pittsburgh he became a fellow in medicine at the Mayo Foundation. In 1931, he received the degree of Master of Science in internal medicine from the University of Minnesota and became a full professor of medicine in the Rochester branch of the University of Minnesota postgraduate school of medicine in 1947. Part of his service in the army in World War II was spent as chief of the Medical Service and director of the Army's Rheumatism Center, Army and Navy General Hospital. He was promoted in 1945 to the rank of colonel.

Dr. Hench has received the honorary Doctor of Science degree from Lafayette College, Washington and Jefferson College, Western Reserve University, the National University of Ireland and the University of Pittsburgh.

One of the founders of the American Rheumatism Association, he was its president in 1940-41 and has been chief editor of the Association's annual *Rheumatism Reviews.* He is also chairman of the American Committee of the Ligue Internationale Contre le Rheumatisme and chairman of the Arthritis and Rheumatism Study Section of the National Institute of Health, United States Public Health Service.

Dr. Hench has a long list of honorary memberships in outstanding American and international scientific and medical societies. Besides sharing with Dr. Kendall the awards mentioned, he received the Scientific Award of the American Pharmaceutical Manufacturers Association and the special citation of the American Rheumatism Association.

The dinner meeting held at the Coffman Memorial Union in honor of Dr. Kendall and Dr. Hench was presided over by Dr. Theodore C. Blegen, Dean of the University of Minnesota Graduate School. The evening's program was initiated by the showing of a movie recording the presentation of the Nobel prize to the two Minnesota professors at Stockholm last December. Participants in the Symposium on Rheumatism held at the University under the cosponsorship of the University and the Minnesota Heart Association, who were present, were next introduced. After the introduction of guests at the head table, an address on the University and Medical Research was given by Dr. Owen H. Wangensteen, head of the Department of Surgery at the University.

Dr. James L. Morrill, President of the University, on behalf of the Regents of the University, presented the special Regents' Citation as follows:

EDWIN CALVIN KENDALL

Distinguished chemist and physiologist, for thirty-seven years leader in biochemistry in the Mayo Foundation of the Graduate School of the University of Minnesota, successful investigator of hormones and metabolism, exponent of the creed of co-operation between laboratory and clinic, devotee to the thesis that progress in basic research is the key to improvement in human welfare—because your brilliant mind and tireless energy have brought surcease from pain and new hope to suffering men and have opened vistas into the unknown in knowledge; and because your career of scientific research exemplifies the ideal in the consummation of practical achievement through intellectual endeavor; the Board of Regents of the University of Minnesota, upon recommendation of its faculties, this twenty-ninth day of November, nineteen hundred and fifty-one, confers upon you, Edward Calvin Kendall, a Special Citation for Distinguished Service.

PHILIP SHOWALTER HENCH

Distinguished alumnus of the University of Minnesota, keen observer of disease-states, example of the ideal physician who combines the application of the available tools of science with the diagnostic skill and therapeutic yearning of the healer of the sick, exponent of teamwork in the investigation and practice of medicine—because your brilliant observations and tireless persistence in the study of rheumatic diseases have culminated in the discovery of new and successful methods of their treatment and of new knowledge as to the mechanism of their occurrence; and because your career as physician and clinical investigator exemplifies the ideal to which others may look for inspiration; the Board of Regents of the University of Minnesota, upon recommendation of its faculties, this twenty-ninth day of November, nineteen hundred and fifty-one, confers upon you, Philip Showalter Hench, a Special Citation for Distinguished Service.

After the citations had been presented, the recipients responded, each with a touch of humor which was delightful.

American medicine is spearheading the fight against those who would lead us into socialism and the welfare state. We all have a great task to further, jointly, our efforts to maintain a free America. We are on the threshold of the greatest progress, perhaps in all history, in the relief of human suffering and the prolongation of human life. The wonder drugs, the developments in the fields of hormone and steroid therapy, modern surgical miracles, all presage a great era of sound health for our people. The hidden workings of the human mind are being revealed. And all this has, in the past, and can, in the future, be effected only if we maintain that spirit which flourishes only under our system of free and unfettered medicine. American doctors accept their obligations to the welfare of our free society, and with God's help will continue to uphold those ideals which have made this nation the hope of freedom-loving people everywhere.—J. STANLEY KENNEY, M.D., Conference of Health Officers and Nurses, Lake Placid, N. Y., June 4, 1951.

AN EDITOR VIEWS MEDICINE

EDWIN F. ABELS
Publisher, The Lawrence (Kansas) Outlook;
Past President, National Editorial Association

WHEN 65,000 individuals and business firms joined with the medical profession in buying advertising space in newspapers of America to advertise the fact that they were in accord with your campaign for freedom, my fellow publishers from one end of this great nation to the other took new courage. Here was unexpected support for the bulwark of Democracy, the non-metropolitan press of America, that has stood against the attacks on our freedoms. I speak of the non-metropolitan press that reaches more than 52 per cent of the people of this nation. Those newspapers that help elect 67 per cent of the U. S. Senators and 69 per cent of the U. S. Congressmen. I refer specifically to the papers printed and circulated in towns of less than 10,000 population and the rural trade areas.

It is literally true that groups of our editors met and talked about this phenomenon of an advertising campaign sparked by the medical profession. There is a logical reason for that surprise. Doctors are highly trained, scientific men. Colleges rightfully place great emphasis on thorough technical training. But some of your schools have entirely neglected a very important subject—that of public relations. Many an editor never hears from the doctor in his town except when the doctor's wife has a bridge party or when the banker's wife has a baby and "Doc" thinks he needs to be mentioned as having helped a bit. Let the editor suggest that "Doc" put his name in a small square on the Elks picnic program and the oath of Hippocrates gets a few modern oaths hooked on to it before the editor gets back to his office.

It has been said before, and I only repeat it, freedom in this nation is being poisoned. It is sick unto death. The editors of the papers I represent have known this fact and have been concerned about it. It never occurred to them to call in the doctor to help cure this case of poisoning. Foolishly, they kept calling on the politicians, some of the very men who were mixing the libation. What a thrill it was when you men walked in, unannounced, and told the world to count you on the side of freedom, liberty, private initiative and all of the privileges and opportunities that have contributed to the greatness of this nation. Yet it was the natural thing for you to do. History tells us that yours is a profession built by men of courage, vision and great intellect.

A History of Courageous Action

Let's check that very briefly by going back to the origin of true medicine as we know it today—back to that early Greek civilization from whence came some of the greatest thinkers of all times. Starting with nothing except their five senses and keen interpretative faculties they pooled their experiences to form the very beginnings of modern medicine. The sick gathered in the Temple seeking help. It was there that the first hygienic principles were developed and the importance of baths and diet were discovered. In 460 B.C., Hippocrates, the greatest of all the scholars, the philosopher, the son and grandson of physicians, upset many old traditions and dared to follow his own conclusions; an example of courage that has been emulated many, many times through the centuries.

Let's go over into Egypt for another great demonstration of courage. This time it was Ptolomy who made the noteworthy contribution. His dissections of the human body were the basis for the advancement of anatomy and physiology.

Next, to the Roman Empire in 130 A.D. to pay tribute to Galen, the greatest of the Roman doctors. One of his biographers says that he influenced the medical profession for 13 centuries. In my opinion his influence is still being felt, for he was the first to charge a fee of $2,000.

Let's skip the Dark Ages—the time from about 200 A.D. to the beginning of the 15th century. Skip them because the signs today are pointing unmistakably to a crackup of the fundamental principles upon which this nation is founded. Let's admit our political mistakes and help search for a solution, for there is work for every courageous group, every thinking individual. I want to give you a little true story to show that brave men are constantly being trained in your profession. We have in our town the University of Kansas with one of the nation's outstanding schools of Medicine. According to the story, one of the medical students had acquired a reputation for being an exceptionally brave young man. He even admitted that he had an abundance of that particular virtue. His classmates became a bit bored with his bragging. An opportunity to test his courage came when he was being initiated into one of the medical fraternities. The event was planned carefully. It was nearly midnight when he was taken to a deserted farm house where he was led into an empty room back by the flickering gleam of an uncertain flashlight. On a rudely constructed bench of boards placed across a couple of logs was a cadaver. The brave young man was given a lighted candle and told to keep watch. He did not know that his silent companion on the boards had left this vale of tears while sitting in a chair and was now in a prone position only because he was tied down. The initiate sat quietly in his chamber of reflection listening intently as his companions started their car and drove away. All was quiet except for the ticking of his wrist watch and the sound of the Kansas wind as it whistled eerily about the place. Suddenly there was a crash. A large stone

---

Address made before the Conference of Presidents and other officers of State Medical Associations, Atlantic City, New Jersey, June 10, 1951.

came through the window and bounced noisily across the floor. The young medic scarcely moved. Only the candle flickered a bit in the breeze. Next a huge black cat came bounding in through the broken window and the cadaver suddenly raised to a sitting position. The student spoke a bit sternly as he said, "Lay down, you damn fool, I'll put the cat out."

Gentlemen, we recognize in you the courage that is necessary to assist in regaining and preserving our freedoms. You have made a start. Let's not just sit there like the cadaver and wait for someone else to put out the cat. You are teamed with the power of the published word and paired with men who are alert to the growing threat. Chaucer, in his writings many years ago said, "The lyf so short, the craft so long to lerne." Each of us has been busy learning our business and life is so short that we must act now if we are to be effective.

What America needs today, what your profession and my business needs, more than any other one thing that I can call to mind, is men of courage to speak out fearlessly and courageously for what they know to be right. You did it in your advertising campaign and you inspired thousands of others to follow your example. By that campaign you won new prestige. Brave men must hold high the torch of liberty.

Our Duty as Citizens

Our American system of government is based on the right of the individual under the law. It is based upon the tenets of Christianity, the Ten Commandments, the Sermon on the Mount, the Golden rule—aye, on the very principles enunciated by Hippocrates a half century before the birth of Christ. Our system of government is based on reason and common sense and the dignity of man. Our churches are crowded with those who say they believe in the principles of Christianity. Our stores and our places of business are staffed with the folk who fill the pews on Sunday. Yet we are faced with the threat of state control, Socialism, Communism. Everything that is the exact opposite of what we profess to believe. Possibly the old blanket story still holds true.

Out on the plains of our great middle west this old story has long been a favorite. The proprietor at the crossroads store was a pious gentleman. He had numerous verses of scripture tacked up all over the place. He made it a rule that every time he made a sale he would quote a verse of scripture as he punched the buttons on the cash register to ring up a sale. One day a cattleman came in and asked for a saddle blanket. He had just bought a fine horse and a wonderful saddle. He told the storekeeper he wanted a blanket that would fit his new purchases, the best was none too good. The old merchant reached to the top of the pile and pulled off a blanket for $3.95. That wasn't nearly good enough. He reached into the middle of the same pile and pulled out one for $14.75. It, too, was not good enough. The third one, which was pulled from the bottom of the $3.95 pile, was priced at $32.25 and the cattleman bought. The old loafers grouped about the stove leaned forward to hear the verse of scripture when the old merchant rang up the sale. Here is what they heard—"He was a stranger and I took him in."

The pressure under which we are working has kept us so busy that we have become strangers to what is happening in Washington, in our state capitals and even in our local units of government. Like the man who bought the blanket, we are being taken in. So rotten and corrupt has our government become on the national level that it was necessary to fire a five star general in order to divert the minds of the people from the graft and corruption that had been exposed by a congressional committee. A part of that expose of gambling and immorality can be traced back to your town and to my town, for how could there be a national crime syndicate, or gambling syndicate, without local outlets throughout the nation?

I mention this to emphasize the fact that we have not been alert to our duty as citizens. We have calmly accepted the type of government the politicians have wanted us to have, not the kind of government we have a right to demand. As a result of our reticence to speak out bravely for what we know to be right, every freedom we hold most dear is at stake. If you will pardon a couple of personal experiences I want to illustrate what I mean. Back in 1938 I published a story in my newspaper about a certain ultra liberal preacher in my town. I called him a Communist and, as a result, I had a $20,000 libel suit on my hands. In spite of the fact that he had said in my office that he was a member of the Communist party, I was forced to get evidence to prove my assertion. How I got that evidence and the fact that the case never went to trial is interesting but not important here. I want you to know that within the past six months that same preacher was called before the courts of Ohio in a loyalty hearing. That hearing was necessary because he was at the head of one of the largest airports in the state of Ohio adjacent to one of the large industrial districts. It took thirteen years for the Government to get interested in this case.

The other incident I want to mention is that within the past four weeks a friend of mine returned from 24 years of missionary work in China. I wanted a story for my paper. I did not get it but I did get information from him that has made me realize that we, the people, have lost far more of our freedom than we dare admit. The reason I did not get this man's story was because he feared for the life of his friends who are still in China. He saw it happen before he got out of the country. He knew that one little story in a weekly paper just about as far away from China as it is possible to get, telling of the oppression under Communist rule would find its way back to that country in a matter of only a few days and the purge would follow.

I bring these two stories to you to emphasize the fact that we can no longer hide behind the excuse that we are too busy in our business or professions to be interested in politics. In 1938 a man boasted that he was a Communist, proud of it, and that this Government would be overthrown either by or through their work among the youth of America. Thirteen years later, Government authorities started checking on him. A loyal, Christian, American citizen dares not speak because his story would bring death to friends on the other side of the world within a fortnight. How near are we to losing our freedoms when our enemy already has this much power?

The Role of National Groups

Hundreds of our newspapers are not yet alert to the menace of Socialized medicine and other Socialistic-Communistic activities. Hundreds of your members will not speak out in defense of the freedoms they have used to such glorious and beneficial advantage. The same is true in almost every line of business and professional endeavor. Our people must be alert to the threat that is so close upon us and must do something about it. Your organization has made a start.

I am proud of the fact that just about a year ago the members of the National Editorial Association, as part of their annual convention held at Providence, Rhode Island, made a pilgrimage to Plymouth Rock for a rededication service. Representing some 5,500 non-metropolitan newspapers in all parts of the nation, they dedicated the services of those publishers to the principles and ideals upon which this nation was founded. They consecrated themselves anew to the fundamental freedoms of our nation.

It was not just by accident that you found willing hands to help carry your message to the American people. There is a reason why papers with less than 3,000 circulation carried 75 per cent of the tie-in advertising. These are the small town newspapers that are close to the lives and hearts of the people they serve. These same newspapers, today, in many states are leading the campaigns to make hospital facilities available for the young doctors they hope to bring into their communities. These are the newspapers that are actively concerned with government. These are the papers that publish the death notices of those brave boys who are dying on the battlefields in Korea in a war that cannot be won—where the emphasis is only on how many of the enemy can be killed. These are the papers in which the sympathy of the community is extended to the parents. Your representatives, Whitaker and Baxter, made a careful study of the field before they chose so wisely the media to be used in placing your message before the people of America. They concentrated on the group that has ever carried the torch in the fight for freedom's preservation, the vast majority of them placing service to their community and nation ahead of the dollars that might be lured into the cash registers.

Your friends, the publishers, have not stopped in their fight for better government. It is a never ending fight. In our Spring Convention held in New York City in April of this year the National Editorial Association, after the excellent address given by Dr. Louis H. Bauer, chairman of your board of trustees, passed the following resolution:

> "Whereas we believe that an outstanding contribution, during the past year, to the cause of individual freedom and the maintenance of our American way of life has been the Nation-wide campaign by the American medical profession in behalf of freedom for both physicians and the cause of political freedom,
>
> "Therefore, Be It Resolved that we do publicly commend the doctors of our country for their enlightened contribution to the American way of life; and do recognize this public service so ably performed by the American Medical Association, its Officers, its Board of Trustees, its Campaign Committee, and to Clem Whitaker and Leone Baxter, who directed the National Education Campaign of the American Medical Association."

The resolution was passed without a dissenting vote. Today, it is my honor and privilege to bring you greetings from our membership and to compliment you for your firm stand against the socialization of your profession. It is our sincere hope that other national organizations will follow the example set by the great American Medical Association and arouse their membership to the peril that is upon us. The philosophy of our enemies is to divide and conquer. They expect to take us one group at a time. It is the duty and most important function of every national association, whether it be lumber dealers, hardware merchants, men in the various fields of transportation, men in the professions, newspaper publishers, doctors or any and every other type of national organization, to make every effort to block any and all government encroachment on business. We must stand together as a unit when our liberties and freedoms are at stake. This was one of the main themes in the National Editorial Association convention held at Seattle just a few days ago and it has been stressed in practically every meeting of the association during the past decade.

The Spirit That is America

The spirit that is America, and the spirit we must preserve at all cost, is typified by this true story from my native state, Kansas. I would be remiss in my obligation as a citizen if I did not give at least one illustration of the thrilling leadership the medical profession has in Dr. Franklin D. Murphy, dean of the University of Kansas School of Medicine—leadership that helps men to help themselves, thereby gaining strength of character and unity of purpose. Under the date line of April 29 the people of my state were given the story of the opening of the $30,000 hospital in Bird City, a community of 536 people in the high plains country in the northwest part of the state. For 10 years the people in that small community tried to get a doctor. Dean Murphy's rural health plan, that has had national recognition, was the means of solving their problem. The people of Bird City built their hospital by contributions of cash and labor. More than 100 families gave something. It took them four years to get the job done but they now have a modern building, fully equipped; it has a nursery, a surgery room, an X-ray room, rooms for the patients, a kitchen, reception room and all the rest. It's all paid for, it's tax free, for the use of all the people of that little community. Best of all, it has been leased for $1 per year to Dr. D. Dan Ferguson, a 27-year-old graduate of the University School of Medicine who has been practicing there for almost a year. This story has been repeated a score of times in Kansas under the inspiration and guidance of Dean Murphy. In the same manner and with the same spirit that our pioneer forefathers conquered the prairies and forces of nature to lay the foundation for a great state, so Dr. Murphy is today's personification of the Spirit that is America.

For a direct antithesis let's go to the May 7 issue of the *Saturday Evening Post* (the issue will be found in the waiting rooms of many doctors about a year from now) to the article written by Dr. Ernest M. Pippa, "I Was A Surgeon For The Chinese Reds," in which he quotes a leading Communist as saying: "We have dispensed with the sloppy humanitarian viewpoint that wastes valuable time and material on useless dregs of humanity merely because they are sick. We have only one interest and one duty: to keep fit those who are of value to our communist state. These are the ones who will get our attention and our best care. We are not interested in the people of China as they are now. They must die anyway before we can build a new China. To help them to prolong their lives by adequate medical care would not only be a waste but it would retard progress."

There you have the communist way in contrast to what we have enjoyed in this nation. It is true that socialized medicine alone is not communism as it is practiced in China, but we must recognize that it is a big step in that direction. Look what those who advocate socialized medicine did with the dignity of the ordinary bank loan when they launched the RFC.

I will admit readily that this illustration is a bit extreme but when we start down a road it is well to know beforehand just what is at the other end. We have had far too much loose thinking and social planning in this nation. Not knowing all of the facts gets us into trouble quickly. The favorite story of a former chancellor of our University concerned a student who objected to the requirement that he learn to swim. He said he had no time for it and said he could learn to swim by reading about it in a book and studying the pictures. The idea caught the fancy of the swimming instructor who consented to the student's demands and told him to report at the end of the semester ready to swim three times the length of the pool as a test of his knowledge. Two or three evenings before the time for the test the student practiced the various strokes as illustrated in his book by lying on the piano bench, kicking and going through the necessary motions. When the time came for the test he plunged bravely into the deep end of the pool and sank to the bottom. The second time he came sputtering to the surface they yanked him out of the water. When he regained his voice he said that he had committed to memory every necessary detail on how to swim and he would have been successful, too, except he didn't know about the looseness of the water. We have far too many persons who do not know about the looseness of the thinking in political circles.

Our Common Cause

Members of the conference, I ask your pardon for not having properly emphasized the many accomplishments of your great profession. Many of the cures that are now considered routine by you in your everyday work border closely on the miraculous. Never in all of recorded history has the healing art advanced so rapidly by scientific research that has been so basically sound. Much of that advancement has been due to your closely knit organization and exchange of ideas and experiences. Through your efforts during the past 50 years you have given us 20 extra years of life and it didn't just happen by accident. My grandson who was born three months ago can look forward to 67 years of life unless the Socialized medicine politicians steal it from him. I have heard the attacks on the medical profession in legislative halls and have helped to refute them. I am well aware of the criticism that is leveled at you sometimes justly but far more often unjustly. Mostly it comes because of too much professionalism and too little sympathy, kindness and understanding on the part of a busy doctor. But all of this is of minor importance compared to the main issue, socialized medicine: we want none of it.

I have purposely stressed the threat to our freedoms for that is our common cause. Within the past fortnight the same alarm has been sounded in three different state press meetings. In Minneapolis, Minn., Ralph Keller, secretary-manager of the state association and a competent leader, said: "a discouraging number of passes were made at the freedom of the press during the recent session of the Minnesota legislature. The trend is evident in legislation in both state and federal levels." A similar thought was expressed in a press meeting that week in Boulder, Colorado. Again at Elkins, West Virginia, Jim Weir, publisher and veteran association executive, stated it this way: "complacency, indifference and irresponsibility, a creeping disease, is to be seen on all sides, in all the levels. An alert press is not alone sufficient to protect us from the dangers from within and from without. A rebirth of responsibility and a resurgence of freedom is needed."

I am emphasizing today the need for the continued help of the Medical profession to bring about the rebirth of responsibility and the resurgence of freedom that my friend Jim Weir speaks about. I am also extending an invitation to all other groups and national organizations that believe as we do to join with us for we must be united if we win this fight. In far too many places there is a lack of effective leadership either in the medical profession or at the newspaper office. In those places it must come from some other group. Through our combined efforts we must somehow, some way, rekindle in the heart of every true American that spark of patriotism so necessary to good citizenship in our republic. We must never lose sight of the fact that free enterprise made America great and free enterprise will keep America great. We must speak up for America and her institutions at every opportunity. We must ever remember that what a man does for himself dies with him, but what he does for his community, his state, and nation lives on forever in the minds of his fellow men. We must do all within our power to preserve our constitutional form of government. We must live our daily lives to the honor and glory of God whose universal laws are the cornerstone of the nation we love. If we do all of these things, then you and I and those who follow can continue to enjoy the blessings of this great, liberty loving nation.

Medical Economics

George Earl, M.D., Chairman

SENATORS WARN AMA DELEGATES OF STATE SOCIALISM

Senators Robert A. Taft and Harry F. Byrd charged that growth of Federal power perils individual liberties in America and is leading toward state socialism. This warning was voiced to the House of Delegates of the American Medical Association in its Interim Session in Los Angeles last month.

Scoring current trends of government control, Senator Taft said that the fundamental problem before Americans today is "how best to maintain the great progress they have made under liberty. That liberty is threatened by the forces of Communism from abroad and is threatened by growing Socialism and government control at home."

Explains Socialism Meaning

Today's liberty, Senator Taft continued, is threatened by "what is roughly called Socialism." He said:

> "By that I mean the growing power of government in the affairs of all individuals and its increased activity in many fields where it has never heretofore been involved."

He described the increase in government controls by saying that in 1931 the Federal Government conducted 6 per cent of the country's activity. In 1949, before the start of the mobilization program, Washington was spending 10 times as much money as in 1931 and was conducting 18 per cent of the activity. By 1953, he estimated the Government will be spending 38 per cent of the total income.

> "It has undertaken to regulate all industry and commerce and agriculture with great Federal bureaus and huge subsidies. It has taken over functions which were almost exclusively local and it threatens to take over all welfare services through a scheme known as social insurance, which is not insurance but simply more taxation to support free Federal welfare services."

Lauds AMA's Stand

The senator applauded the AMA's efforts to halt the socialistic trends in America, adding that "the doctors are justified in this because the key move of the socialists today is the effort to set up a Federal system of socialized medicine."

> "The Government proposes to collect six or seven billion dollars, mostly in payroll taxes from workmen, and set up a vast Federal bureau to employ nearly all the doctors in the country to furnish free medical service to all the people, including the great majority who are perfectly able to pay for it themselves . . .
>
> "We cannot impose on the hard-working people of the country a burden so great to support the non-workers that it reduces their incentive and their standards of living."

Socialism Has False Blueprint

Senator Taft asked the purpose of this vast expansion of government activity, answering that supposedly it is for the welfare of the man of low and middle income. "Socialism draws a beautiful blueprint, but it utterly destroys the incentive of the individual manufacturer or the individual workman," he said. "In its efforts for equality, it reduces everyone to the dead level of mediocrity. New ideas are discouraged."

> "The more powerful a government becomes, the stronger its propaganda in behalf of more power. The trend cannot be stopped unless you are willing to elect both a President and a Congress who believe that the maintenance of liberty is the first and most essential consideration for progress."

Byrd Cites Fiscal Weakness

Senator Byrd of Virginia told doctors that the "one overshadowing characteristic of the administration now in Washington is fiscal weakness and irresponsibility. From this springs the demand for confiscatory taxes, stifling controls and centralization."

Stating that the administration is guilty of great fiscal irresponsibility and that it is being further exploited by political camp followers who would centralize all power and purse control in Washington, Senator Byrd warned:

> "From these come a deadly assault on the free enterprise system, the creeping socialism and the scandals which Thomas Jefferson foresaw when he said: 'I believe that a consolidated government would become the most corrupt government on earth.'"

Senator Byrd said that America's most inflated item today is the Federal Government itself, and continued:

> "Inflation is conceived and born in Washington. Only the Federal government can spend in unlimited amounts. It alone determines the value of money and the extent of credit. A Federal bond is a first mortgage on all the property owned by every American citizen.
>
> "Once the American dollar goes down, we will enter an age of international darkness. The American dollar is the only thing today that is holding the world together.
>
> "What nation can carry the standard if we fail? Without its light, freedom and progress would perish from the earth. We must not fail."

HOUSE OF DELEGATES REVISES HESS REPORT

The House of Delegates of the American Medical Association, at its December interim session, adopted a policy statement on physician-hospital relations which supplants the controversial "Hess Report." The following principles for guidance of individual practitioners and medical societies in controversies over employment of doctors by hospitals were set forth:

1. A physician should not "dispose of his professional attainments or services" to any hospital or institution under conditions whereby such services are resold.

2. If a hospital does not sell the physician's services, the financial arrangement between them may be placed on any mutually satisfactory basis. Remuneration may be made for teaching or research not only by hospitals but by corporations and other lay bodies.

3. Specialties of anesthesiology, pathology, physical medicine and radiology—the ones chiefly concerned by this AMA policy—are recognized as an integral part of medical practice.

Half Million More to Medical Schools

The House of Delegates also voted to contribute another $500,000 to the American Medical Education Foundation, which has been raising funds within the organization for the unrestricted use of the nation's medical schools.

Approximately $640,000 has been turned over so far by the Foundation to the National Fund for Medical Education. This money, 56 per cent of the amount dispersed by the Fund, was divided among the seventy-nine approved medical schools for use at the discretion of the deans of the institutions.

MEDICAL SERVICE CONFERENCE DATES SET

The National Conference on Medical Service will hold its annual meeting at the Palmer House, Chicago, on Sunday, February 10, 1952. Harlan English, M.D., Danville, Illinois, is this year's chairman, and the Illinois State Medical Society is acting as host.

The tentative program is as follows:

AMERICA'S NEXT SOCIAL AND HEALTH CRISIS

I. Care of the Aged with Chronic Disease
  (A) Size of the Problem—to be presented by an outstanding insurance actuary
  (B) One Partial Solution—to be presented by a representative of a city welfare department

Luncheon

"Our Citizens and Their Doctors"—HON. EVERETT MCKINLEY DIRKSEN, U. S. Senator from Illinois

II. Veterans' Medicine
  (A) "Future Implications of Veterans' Medical Care"—GEORGE CRAIG, Past Commander of the American Legion
  (B) "Unusual Problems in Veterans' Medical Care"—ADMIRAL JOEL T. BOONE, Chief Medical Officer, Veterans Administration, Washington, D. C.
  (C) "Hometown Veterans' Care—A Success or a Failure?"—(Speaker to be announced)

BRITISH M.D.'s CALLED "ARM OF GOVERNMENT"

The piquant phrases of the *Wall Street Journal* have once again been used forcefully to bring out the underlying truths in the latest request of British doctors that the government fine any patients who fail to take the doctors' pills. *The Journal* feels that this step is perfectly logical since "these doctors are just as much an arm of the British government as the bobby on the street corner. They are paid by the government to regulate the public health just as the bobby is to regulate traffic. In either case if the citizens don't carry out instructions the orderly plans are snarled up."

Cannot Shirk Duty

Describing the National Health Service as having gone so far as to take on the duty of running part of the citizens' affairs, the *Journal* decides that the health service cannot shirk its duty, and so it must also regulate a penalty for not obeying any rules established:

> "It's a well established principle that when a government takes on the duty of running any part of its citizens' affairs it is necessary and proper for the government to use its powers of compulsion to see that the people do what the government knows they should do. If the government has the duty to protect the people's health, it surely shirks its duty if it permits people not to take the pills ordered by regulations."

Thus, says the *Journal,* the British doctors are on sound judicial, historical and sociological ground. "And they are really being very reasonable about it. All they want the government to do is fine a patient 10 shillings ($1.40) the first time he violates an order to stay in bed, eat milk toast or wear his government-provided false teeth. Even for a second offense the fine is to be only a pound ($2.80). With commendable British restraint the doctors have refrained from asking for jail sentences."

In spite of the overtone of lightness in the *Journal's* comments, the serious meaning of the situation is clear, and can serve as an adequate warning to those who still think that a government-controlled health insurance program would be advisable for America. This odd proposal for compulsion has all the earmarks of socialistic logic. The *Journal* concludes:

> "We are sure Parliament will act promptly on this request. It's hardly cricket for the medical planner to have the responsibility for regulating the patient's health without the authority to regulate the patient."

VOLUNTARY HEALTH PROTECTION

Reflecting the continuing desire of Americans to choose their own methods of meeting the costs of illness, all forms of voluntary health protection scored tremendous gains in 1950 to set new records, the Health Insurance Council reports in the fourth annual edition of its Survey of Accident and Health Coverage in the United States.

The council survey shows that hospital expense coverage was held by 76,961,000 persons at the end of 1950, a gain of 17 per cent over the figure of 66,044,000 estimated for the year previous. The number of persons protected under hospital coverage has more than doubled since the end of the war.

Surgical expense insurance gained 32 per cent from 41,143,000 to 54,477,000.

Medical expense coverage gained 28 per cent from 16,862,000 to 21,589,000.

The council estimates that the 1950 total was equivalent to coverage on approximately 60 per cent of employed civilian population. The figures do not include the individuals covered solely by government insurance under compulsory plans, but do include all insurance companies, Blue Cross, Blue Shield, fraternal societies, local medical societies, industry, universities and others. —Insurance Economics Survey, October, 1951.

PROBATION OF MINNEAPOLIS WOMAN REVOKED FOR CRIMINAL ABORTION

Re State of Minnesota vs. (Mrs.) Val A. Ramer

On December 15, 1951, the probation previously granted by the Hon. Rolf Fosseen, Judge of the District Court of Hennepin County, on August 22, 1950, to Mrs. Val A. Ramer, seventy-seven years of age, 4311 Portland Avenue, Minneapolis, on a charge of abortion, was revoked. The defendant, Ramer, admitted to Judge Fosseen that she had committed two criminal abortions while she was on probation. Mrs. Ramer had entered a plea of guilty on June 6, 1950, to an information charging her with the crime of abortion. At that time, Mrs. Ramer also admitted a previous conviction in 1936. Judge Fosseen sentenced Mrs. Ramer on August 22, 1950, to a term of not to exceed three years in the Women's Reformatory at Shakopee, Minnesota, but, because of her age, suspended the sentence and placed Mrs. Ramer on probation for a period of five years.

Mrs. Ramer was arrested on November 28, 1951, following a routine visit to her home by an officer of the Hennepin County Probation Office. At that time, a young woman, who was found in the kitchen of Mrs. Ramer's home, ran outside and fled in an automobile driven by a young man. Various medical instruments were found on a tray in the oven of the defendant's home. Subsequent investigation by the Minneapolis Police Department, Hennepin County Probation Office and the Minnesota State Board of Medical Examiners disclosed that Mrs. Ramer, on November 28, 1951, had aborted a thirty-three-year-old St. Paul woman, who admitted that she was the person who had fled Mrs. Ramer's home on that morning. The same woman admitted that she paid Mrs. Ramer $50.00 two weeks previously, when she first attempted the abortion. She had also been aborted by Mrs. Ramer six or seven years ago. The investigation also disclosed that the defendant Ramer had aborted a twenty-six-year-old unmarried Minneapolis woman on November 27, 1951, for which she was paid the sum of $50.00.

The defendant Ramer was first convicted of the crime of abortion in 1936. On October 30, 1934, the grand jury of Hennepin County returned an indictment charging a Minneapolis physician and the defendant Ramer, with the crime of abortion. In April, 1936, the defendants were placed on trial and both found guilty of abortion. On May 5, 1936, each defendant was sentenced to a term of not to exceed four years, the sentences being stayed and both defendants placed on probation.

MINNEAPOLIS PHARMACIST CONVICTED OF CRIMINAL ABORTION

Re State of Minnesota vs. Meyer S. Furman

On November 26, 1951, Meyer S. Furman, forty-four years of age, 2797 Xerxes Avenue South, Minneapolis, was sentenced by the Hon. Harold N. Rogers, Judge of the District Court of Hennepin County, to a term of not to exceed four years in the State Prison at Stillwater, for the crime of abortion. Judge Rogers stayed execution of the sentence for two years, and placed Furman on probation. Furman, a registered pharmacist, operates the Grant Street Pharmacy at 1333 Nicollet Avenue, Minneapolis.

Furman and Mrs. Clara Olga Anderson, 1728 Bryant Avenue North, Minneapolis, were arrested in September following an investigation by representatives of the Minnesota State Board of Medical Examiners and Minneapolis police officers. That investigation disclosed that $350 was paid to Furman on September 7, 1951, for an abortion on a twenty-one-year-old Swift County girl. The abortion was performed by Mrs. Anderson, who admitted receiving $150 of the money, with Furman pocketing the balance. Furman made the arrangements for the abortion, driving the patient to Mrs. Anderson's home from his drug store, and when no miscarriage resulted, the abortion was repeated on September 21, 1951, by Mrs. Anderson. Furman, who entered a plea of guilty on October 15, 1951, to an information charging him with the crime of abortion, admitted to the Court, prior to being sentenced, that he had referred three patients to Mrs. Anderson for abortions. Furman also admitted that he had been in previous trouble for selling liquor without a license. The records in the Municipal Court in Minneapolis disclose that on April 28, 1939, Furman paid a fine of $100 for selling liquor without a license. On May 24, 1940, Furman was found guilty of selling non-intoxicating malt liquor without a license and was sentenced to ninety days in the Minneapolis Workhouse. Furman filed a notice of appeal but subsequently dismissed the appeal, and on September, 30, 1940, entered the workhouse to serve his sentence. On February 12, 1949, Furman admitted, in a written statement to Minneapolis police officers, having referred "about twenty-five" girls to Martin Peter Schmit, who was sentenced on March 17, 1949, to a term of not to exceed four years in the State Prison at Stillwater for the crime of abortion. Furman graduated from the College of Pharmacy of the University of Minnesota in 1927. Furman's abortion activities have been called to the attention of the Minnesota State Board of Pharmacy.

Furman's co-defendant, Mrs. Clara Olga Anderson, entered a plea of guilty on October 23, 1951, to an information charging her with the crime of abortion. The Court referred her case to the Probation Office for investigation and the imposition of sentence was set for December 17, 1951.

MINNEAPOLIS WOMAN SENTENCED TO 8-YEAR TERM FOR CRIMINAL ABORTION

Re State of Minnesota vs. Clara Olga Anderson

On December 17, 1951, Hon. Harold N. Rogers, Judge of the District Court of Hennepin County, sentenced Clara Olga Anderson, fifty-three years of age, 1728 Bryant Avenue North, Minneapolis, to a term of not to exceed eight years at hard labor in the Women's Reformatory at Shakopee on a charge of abortion.

On October 23, 1951, Mrs. Anderson had pleaded guilty to an information charging her with the crime of abortion, and also with having had two previous convictions for a similar offense, one in 1943, and another in 1946. A plea by the defendant's attorney that the defendant be given probation was opposed by legal counsel for the Minnesota State Board of Medical Examiners and denied by Judge Rogers. Mrs. Anderson and Meyer S. Furman, 2797 Xerxes Avenue South, Minneapolis, were charged as codefendants with the crime of abortion in a complaint issued in September, 1951. Investigation by representatives of the Minnesota State Board of Medical Examiners and Minneapolis police officers, disclosed that the defendant Anderson had twice attempted to do an abortion on a twenty-one-year-old Swift County girl. Mr. Furman had made the arrangements for the abortion on both occasions and accompanied the girl to the defendant Anderson's home. A sum of $350 was paid to Furman for the abortion, $200 of which he kept himself and the remainder was paid to the defendant Anderson. When the girl later was hospitalized the case was called to the attention of the authorities.

The defendant Anderson has two previous convictions for the crime of abortion in the District Court of Hennepin County. After entering a plea of guilty on March 25, 1943, to an indictment charging her with the crime of abortion, Mrs. Anderson was sentenced to a term of not to exceed four years in the Women's Reformatory at Shakopee. However, the sentence was stayed on condition that the defendant serve one year in the Women's Detention Home and then Mrs. Anderson was placed on probation for a period of three years. Again on December 28, 1946, Mrs. Anderson entered a plea of guilty in the District Court of Hennepin County to an information charging her with the crime of abortion, and also having a previous conviction for abortion in 1943. On the same date she was sentenced to a term of three years at hard labor in the Women's Reformatory at Shakopee. Mrs. Anderson has no license to practice any form of healing in the State of Minnesota.

THE ECONOMIC VALUE OF HIGH QUALITY MILK

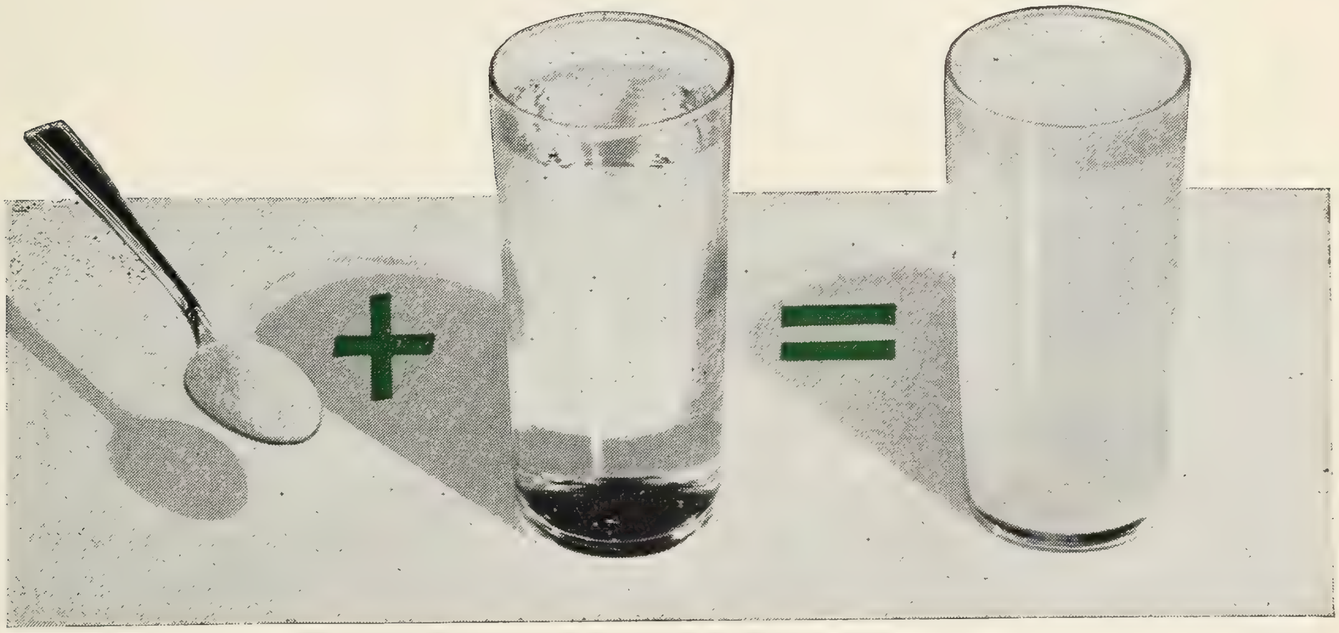
(Continued from Page 45)

recently said, "Of all the factors of man's environment, none is more important to his welfare than food. Of all foods, none is more important than milk." Nutritionists tell us that one-fourth of our daily food requirements should come from dairy products, yet studies of present trends in the per capita consumption of some dairy products show that we are not in all cases maintaining this one-fourth proportion. The consumer is the one who dictates the world standards, and if this quality is not maintained, the consumer loses interest in the product and looks for a substitute. The present Grade A regulation which is being promulgated in Minnesota was required by the demands of the public that Grade A dairy products be made available to them. In 1900 the average American had to work twenty-seven minutes to earn a quart of milk, and this quart was dipped from a can. Today he receives a safe high-quality product delivered with dependable service right to his home for only nine minutes of work.

High quality of dairy products has definite economic value to the public. The dairy industry affects a considerable proportion of our people, provides nearly one-third of our agricultural income and supplies one-fourth of our food supply. The perpetuation of this industry depends so much on the high quality of its products that no producer, the processor, the consumer and the doubt should be left in our minds of the tremendous economic value of high quality milk to the public.

Normohydration

FOR BOWEL REGULATION



Typically, the constipated stool is dehydrated, whereas the diarrheal stool or that induced by salines and irritants is hyperhydrated, containing free water.

When Metamucil is employed for the management of constipation, it is mixed in a full glass of cool liquid. The ingested liquid containing the mucilloid promotes normohydration.

METAMUCIL® is the highly refined mucilloid of Plantago ovata (50%), a seed of the psyllium group, combined with dextrose (50%) as a dispersing agent. G. D. Searle & Co., Chicago 80, Illinois.

AMERICAN COLLEGE OF CHEST PHYSICIANS

The fifth annual Postgraduate Course in Diseases of the Chest sponsored by the Council on Postgraduate Medical Education and the Pennsylvania Chapter of the American College of Chest Physicians and the Laennec Society of Philadelphia, will be presented at the Warwick Hotel, Philadelphia, Pennsylvania, March 24 to 28.

A program covering the entire field of heart and lung disease is being arranged. Dr. Chevalier L. Jackson, Philadelphia, president of the American College of Chest Physicians, is chairman of the postgraduate course committee.

Physicians interested in attending the postgraduate course can communicate with the Executive Offices, American College of Chest Physicians, 112 East Chestnut Street, Chicago 11, Illinois.

AMERICAN COLLEGE OF SURGEONS SECTION MEETING

A three-day sectional meeting of the American College of Surgeons will be held at the Radisson Hotel in Minneapolis, Minnesota, on March 24, 25 and 26.

The program will include two days of scientific sessions at the Radisson Hotel and a day of teaching clinics and demonstrations in Minneapolis hospitals. Distinguished speakers will present papers, panels and symposia on current surgical problems, and extensive programs for specialists in opthalmology and otolaryngology have been prepared for March 25. New surgical motion pictures will be shown, including several which were prepared especially for the Cine Clinics at the 1951 Clinical Congress, and also a stereoscopic colored film on radical resection for carcinoma of the stomach, which is attracting a great deal of attention wherever it is shown.

Dr. Harvey Nelson and his Committee on Arrangements have made extensive preparations to assure a good meeting and a warm welcome to Minneapolis for all visiting surgeons. Hotel accommodations may be obtained by writing to Mr. Neil Wilsey, Front Office Manager in Charge of Reservations, Radisson Hotel, Minneapolis 2, Minnesota.

SUMMER CAMP FOR DIABETIC CHILDREN

A summer camp for diabetic children will be opened for the fourth season under the auspices of the Chicago Diabetes Association, Inc., from July 1 to July 22 at Holiday Home, Lake Geneva, Wisconsin.

In addition to the regular personnel of the camp, there will be a staff of dietitians and resident physicians, trained in the care of diabetic children, furnished by The Chicago Diabetes Association.

Boys and girls, ages eight to fourteen years, inclusive, will be accepted at a fee of $120 (which covers the three-week camping period and transportation from Chicago). Fee reductions may be arranged when considered necessary.

Physicians are requested to notify parents of diabetic children and to supply the names of children who would like to attend camp. Applications may be obtained from, and inquiries should be addressed to the Service Unit, Chicago Diabetes Association, 110 South Dearborn Street, Chicago 3, Illinois.

CHICAGO OPHTHALMOLOGICAL SOCIETY

The Chicago Ophthalmological Society has announced that the fourth annual Clinical Conference will be held February 21 to 23 at the Drake Hotel. The first day will be devoted to surgical clinics at various Chicago hospitals. On the following days there will be symposiums on cataract surgery and recent advances in therapeutics, followed by round table luncheons. Additionally there will be lectures concerning neuro-ophthalmology, ocular pharmacology, nystagmus, provocative tests in glaucoma and the secretion of aqueous.

Further information concerning the conference may be obtained from Miss Maud Fairbairn, 8 W. Oak Street, Chicago 10, Illinois.

POSTGRADUATE ASSEMBLY

Los Angeles' largest annually held medical meeting—the Postgraduate Assembly and Convention, sponsored by the Alumni Association of the College of Medical Evangelists School of Medicine—has been scheduled for March 2-4, 1952, at the Biltmore Hotel. This convention is termed the "best in the West."

The 1952 convention features such nationally prominent men as U. S. Army's Major General George Armstrong; Lahey Clinic's Drs. Sara Jordan, Martin Tracey and John Norcross; A.M.A.'s Secretary and General Manager Dr. George Lull; Joslin Clinic's Dr. Priscilla White; Cornell Medical School's Dr. Harold Wolff and Mayo Clinic's Dr. Giles Koelsche,* to mention some of the thirty-seven scheduled to lecture and take part in panel discussions.

Short courses in therapeutics, internal medicine, pediatrics, roentgenology, dermatology, psychiatry, surgery, otolaryngology, urology, proctology, anesthesiology, and obstetrics and gynecology are to be given on March 5, 6 and 7. Educators of the West's medical schools will serve on the faculty for these sessions.

For further information, write Evelyn R. Strachan, Managing Director, 312 North Boyle Avenue, Los Angeles 33, California.

---

*Giles A. Koelsche, M.D., will speak on "Current Concepts of the Treatment of Asthma."

Do You Have Investment Income?

First Investor: "I feel quite satisfied with my investments—last year I had an average return of about 5%."

Second Investor: "Well, I averaged about 3% with very safe investments, and the income is all mine."

First Investor: "I don't know what you mean—the 5% return is all mine, isn't it?"

Second Investor: "Aren't you forgetting to consider the federal income tax you must pay on your return? Even with this year's taxes your investment income will be under 3%. It may be less than that with next year's taxes."

First Investor: "What about the income tax on your 3% return?"

Second Investor: "My income tax payments are limited to professional earnings. My investment income is tax-exempt because I buy Municipal Bonds."

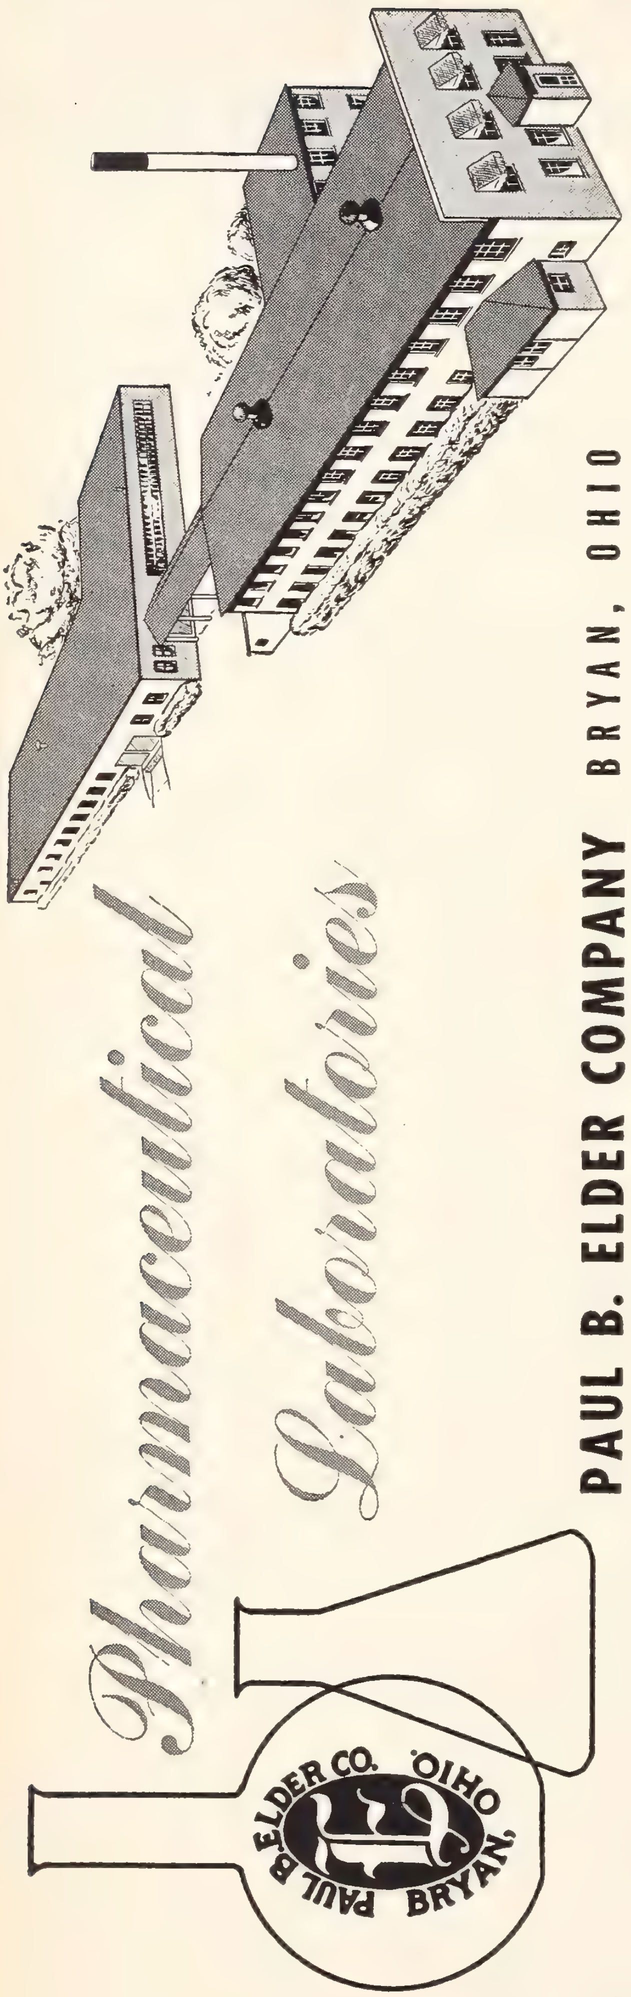
CONTINUATION COURSES

Therapy of Cardiovascular Diseases.—The University of Minnesota will present a continuation course on therapy of cardiovascular diseases February 1 to 16. The course is intended especially for general physicians and will be presented at the Center for Continuation Study. Dr. Charles P. Bailey, professor of surgery, Hahnemann Medical College, Philadelphia, will be the visiting faculty member for the course. He will also give the annual Phi Delta Epsilon Lecture on the evening of Thursday, February 14. His subject at that time will be "Recent Advances and Future Trends in Cardiovascular Surgery." Dr. Bailey is well known throughout medical circles for his work on surgery of rheumatic valvular heart disease. He will report on this work in a lecture in the continuation course.

Dermatology.—Dermatology will be the subject of a continuation course for general physicians to be presented by the University of Minnesota, February 28 to March 1. Dr. Arthur C. Curtis, professor and chairman of the Department of Dermatology, University of Michigan, will be the visiting faculty member for the course. The course will be presented under the direction of Dr. Henry E. Michelson, chairman of the Division of Dermatology at the University of Minnesota.

X-Ray for General Physicians.—The University of Minnesota will present a continuation course in x-ray



Pharmaceutical Laboratories
PAUL B. ELDER COMPANY BRYAN, OHIO
PAUL B. ELDER CO. BRYAN, OHIO

for general physicians at the Center for Continuation Study on March 3 to 5. The course will be under the direction of Dr. Leo G. Rigler, professor and head of the Department of Radiology. Special emphasis will be placed on x-ray techniques, x-ray diagnosis of fractures, other bone lesions and pulmonary lesions. In addition to lectures on these subjects, practical demonstrations will be held. The registrants for the course will be invited to bring their own films to the course for discussion.

BLUE EARTH COUNTY SOCIETY

The Blue Earth County Medical Society held its annual meeting at Mankato on December 10 and elected the following officers: Dr. Robert B. Engstrom, president; Dr. John C. Mickelson, vice president, and Dr. William S. Chalgren, secretary-treasurer, all of Mankato. Dr. John C. Vezina, Mapleton, was named delegate to the Minnesota State Medical Association.

CLAY-BECKER COUNTY SOCIETY

Officers elected at the annual meeting of the Clay-Becker County Medical Society at Detroit Lakes on December 8 were as follows: Dr. V. D. Thysell, Hawley, president; Dr. A. S. Midthune, Lake Park, vice president, and Dr. William C. Dodds, Detroit Lakes, re-elected secretary-treasurer.

MOWER COUNTY SOCIETY

This year, 1952, is the fiftieth anniversary of the Mower County Medical Society. The society, which was founded on October 3, 1902, will be the sponsor this year of the annual meeting of the Southern Minnesota Medical Association to be held at Austin in September.

President of the society is Dr. L. F. Twiggs, with Dr. T. M. Seery as vice president and Dr. F. H. Rosenthal as secretary-treasurer, all from Austin.

RAMSEY COUNTY SOCIETY

New officers of the Ramsey County Medical Society, elected at a meeting in Saint Paul on November 26, are Dr. J. P. Medelman, president, succeeding Dr. F. G. Hedenstrom; Dr. P. F. Donohue, president-elect for 1953, and Dr. Laurence D. Hilger, re-elected secretary-treasurer. All are from Saint Paul.

RED RIVER VALLEY SOCIETY

At the annual meeting of the Red River Valley Medical Society at Crookston on December 11, the following officers were elected: Dr. M. D. Starekow, Thief River Falls, president; Dr. George S. Boyer, Crookston, vice president, and Dr. R. O. Sather, Crookston, re-elected secretary-treasurer. Dr. L. N. Dale, Red Lake Falls, was the retiring president.

Forty physicians attended the meeting, at which the main topic for discussion was the legal aspect of various medical problems. It was decided to appoint a committee to develop a code governing the relations of the medical profession with hospitals, the press and radio.

Woman's Auxiliary

PRESIDENT-ELECT REPORTS ON STATE PRESIDENTS CONFERENCE

Mrs. C. L. Sheedy
President-Elect

Attending the eighth annual conference of state presidents, presidents-elect and national committee chairmen is an exciting experience, especially when one is trying to land at the Chicago Airport with seven small tornadoes dancing in attendance. One just knew that, with such a stimulating beginning, this was no ordinary conference. It is a pleasure to meet at last, in person, these pen pals of ours who have spurred us on to such goals. When we talk to them and find them mindful of our problems, we realize how much effort and time they must spend to guide us in the right direction.

The conference will be reported in detail in *The Bulletin,* and Dr. Walter Judd's very fine speech will be distributed to the Auxiliary members, so I wish to tell you some of the thoughts left with us by Mr. Edward O'Connor, Managing Director of Insurance Economic Society of America, whose organization is devoted to the study of social insurance. He quoted Winston Churchill's statement, "Free enterprise has its faults, but it is much better than Socialism with its blessings of misery." Fortunately, sufficient people have come along and stressed a positive dislike for the further development of Socialism. We have gone so far down the path of hand-out state, he continued, that it is impossible to shoot Santa Claus, but I do believe we have begun to sober him up.

We are in a great epic struggle in this country. It is not the old-time contest between the Republicans and Democrats, or what political system works better; it is not a struggle to make democracy work, but to destroy it, not to make it equitable and beneficial to all, but to substitute a system entirely different from that which we have lived and prospered under for one hundred and fifty years.

This situation exists because we have all been smug and complacent. We have taken our freedom for granted. We have assured ourselves that the United States is the greatest nation in the world, that we are God's chosen and that no evil can come to us. But, all of the time, we are being blinded by our own reflection, either being unwilling or unable to see that those things that could not happen here have actually happened. A whole generation has been taught that the world owes them a living; that the government can provide a job for everyone from the cradle to the grave, a doctor at your side and government pills when you are sick, a nice funeral when you die, a beautiful plot in the cemetery.

Our problem today is to help the public differentiate between true and false liberalism and get out of that dangerous habit of succumbing to propaganda, and following the chant of the auctioneer. Propaganda is an art which has been fully developed in this country during the past twenty years. Its potency has been amply demonstrated in other lands.

The proponents of socialized medicine and sickness compensation never tire of beating the drums for their socialistic wares and never tire of subjecting the public to a barrage of twisted facts. They would destroy the most successful medical system the world has ever known and replace it with a system that has never worked anywhere. They fail to understand they cannot legislate health into being any more than you can create temperance by voting in the Volstead Act.

Mr. O'Connor closed by telling us that the freedom which we enjoy is not a permanent possession. It did not come as the result of a hand-out, nor is it self-perpetuating. Freedom is not free and it never was and never will be. It has a price tag: it requires eternal vigilance, alertness to expose every threat and to be prepared to fight those misguided individuals who would deprive us of our heritage in this country, which was built by men who relied on themselves.

We hold our destiny in our hands. There is a crooked and rocky road to slavery with its rosy promises and horrible realities and there is the straight road, the tried and proven road of freedom, the American way. We must make the decision. Do we want to be free people or slaves of the State? The hour is late, the time for action is NOW.

I am sorry not to be able to quote you the entire speech, but I am sure, with what little I have given you, you agree that Mr. O'Connor gave us much to reflect upon.

Needless to say how proud Mrs. Moersch, Mrs. Bakkila and I were of Mrs. Wahlquist, who always in her charming manner conducts with such enthusiasm and draws everyone into the spirit of her theme for this year, "Working Together for Health."

NICOLLET-LE SUEUR HOLDS MEETING

Dr. Burton P. Grimes, Superintendent of the St. Peter State Hospital, spoke on "Mental Health" at a luncheon meeting of the Nicollet-Le Sueur County Medical Auxiliary on October 15 in St. Peter, Minnesota. About thirty-five auxiliary members and guests heard Dr. Grimes' discussion of various aspects of mental health.

The personal attitudes of the patient are important in the treatment of any disease in which the patient's cooperation must be elicited. The more chronic the illness, the greater importance these personal factors assume. Osler summed up the situation in tuberculosis when he said, "It is just as important to know what is in a man's head as what is in his chest if you want to predict the outcome of his pulmonary tuberculosis."—JEROME HARTZ, M.D., *Public Health Reports,* October 6, 1950.

In Memoriam

A. W. ADSON

The following memorial to the late Dr. A. W. Adson, of Rochester, was incorporated in the report of the Council of Medical Service of the American Medical Association to the House of Delegates assembled in Los Angeles, California, in December, 1951.

MEMORIAL TO DR. A. W. ADSON

This report would not be complete without a word of appreciation of the services of Doctor Adson who was stricken while attending the North Central Conference in Minneapolis and died the following day, November 12, 1951.

In addition to his outstanding scientific attainments, he gave unstintingly of his time and energy to perpetuate and further the high standards of the medical profession.

Doctor Adson was a leader in the creation of the Council on Medical Service in 1943 and served on the Council from its origin until 1948. Part of that time he was its Vice Chairman and more recently he served as chairman of the Council's Committee on Prepayment Hospital and Medical Service.

He will be missed by all members of the Council, by the members of the House of Delegates, and by his many friends throughout the country who have had the privilege of his counsel and friendship.

James R. McVay, *Chairman*
Mr. Thomas A. Hendricks, Secretary

GEORGE CHARLES BRUTSCH

Dr. G. C. Brutsch, of Minneapolis, died November 9, 1951, at the age of fifty. He was born in Ceylon, Minnesota, in 1900.

He was a member of the Class of 1931 of the University of Minnesota Medical School and had practiced in Minneapolis since his graduation.

He was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Brutsch is survived by a brother, Elmer, of Estherville, Iowa, and four sisters.

AXCEL CONRAD BAKER

Dr. A. C. Baker, a physician for nearly fifty years at Fergus Falls, Minnesota, died December 7, 1951, at the age of seventy-seven.

Born in Rochester, Minnesota, September 28, 1874, he attended the University of Minnesota where he obtained a B.S. degree. His M.D. degree was obtained from Northwestern Medical School in 1901. He interned for two years at Wesley Hospital in Chicago.

Dr. Baker was a member of the Park Region District and County Medical Society, the Minnesota State Medical Association and the American Medical Association. He was also a Fellow of the American College of Surgeons and had served as President of the Northern Minnesota Medical Association.

Dr. Baker is survived by his wife Katharyn H. Baker; two sons, Norman of Fergus Falls, Charles of Belle Fourche, South Dakota, both of whom are physicians, and two daughters, Kathryn (Mrs. Robert) Hyslop of Fergus Falls and Mary (Mrs. Harold) Mattlin of Coronado, California.

F. R. CROSON

Dr. F. R. Croson, formerly of Proctor, Minnesota, died on November 7, 1951.

Born at Aledo, Illinois, he received his medical education at Northwestern University Medical School, graduating in 1918. He was associated with Dr. Webber in the Missabe Hospital and was a member of the St. Louis County Medical Society during his stay in Minnesota.

Dr. Croson was at one time president of the Kansas State Medical Association and had practiced in Clay Center, Kansas, from 1925 until he retired from active practice last summer.

RALPH T. EDWARDS

Dr. Ralph T. Edwards, formerly of Elysian, Minnesota, died October 12, 1951, at Big Fork, Montana, where he had been living with a daughter since his retirement from active practice several years ago.

Dr. Edwards was born near Plymouth, Illinois, April 22, 1872. He attended Pomona College at Claremont, California, and graduated from Knox College, Galesburg, Illinois, with an M.A. degree in 1899. He graduated from Johns Hopkins medical school in 1904.

He was associated with the U. S. Bureau of Science at Manila from 1905 to 1908 and was Director of the Government's Serum Laboratory at Phrapatoom from 1908 to 1910. After practicing at Galesburg, Illinois, a year; at Warsaw, Illinois, a year; at Ceylon, Minnesota, three years; at Manila, three years, and in Siam, two years, he settled in Elysian, Minnesota, where his special interest was directed to Ophthalmology.

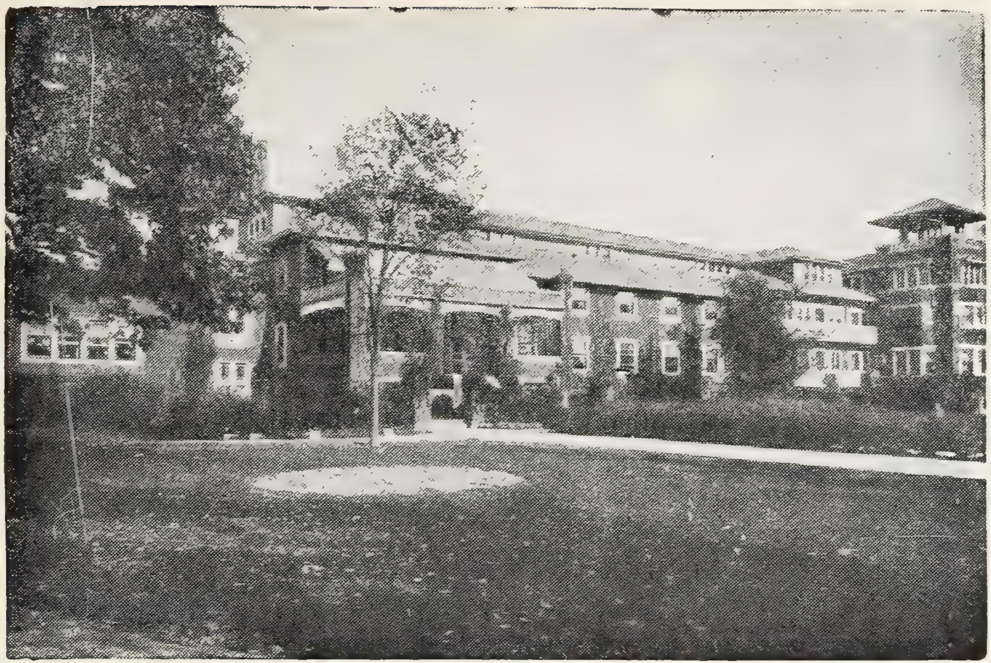
Dr. Edwards was a member of the Blue Earth County Medicial Society, the Minnesota State Medical Association and the American Medical Association.

He is survived by two daughters, Mrs. Mary E. Jung, of San Diego, and Emma H. Edwards, of Big Fork, Montana; and one son, R. Stanley Edwards, of Chagrin Falls, Ohio.

EVERET FLOYD GRAVE

Dr. E. Floyd Grave, founder of the Medical Arts Clinical Laboratory in Minneapolis, died December 20, 1951, at the age of sixty-seven.

He was born in Monrovia, Indiana, August 13, 1884. He obtained a B.S. degree from Carleton College in 1908 and graduated from Johns Hopkins University in



North Shore Health Resort

Winnetka, Illinois

on the Shores of Lake Michigan

A completely equipped sanitarium for the care of
nervous and mental disorders, alcoholism and drug addiction
offering all forms of treatment, including electric shock.

SAMUEL LIEBMAN, M.S., M.D.
225 Sheridan Road **Medical Director** **Phone Winnetka 6-0211**

1914. He interned the following year at the City and County Hospital in Saint Paul. He took postgraduate training at Minnesota and Wisconsin State Universities in laboratory procedure and served as a major in World War I. He was pathologist at Asbury, St. Barnabas, Eitel and the Minneapolis Veterans Hospitals.

Dr. Grave was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association. In 1939 he was elected a fellow of the American Society of Clinical Pathologists.

Dr. Grave is survived by his wife, Katherine M., a daughter, Katherine Ann, and a brother, Thomas H. Grave, of Gresham, Oregon.

WALDO N. GRAVES

Dr. W. N. Graves of Duluth died on December 5, 1951, at the age of fifty-three.

Dr. Graves was born at Indianola, Iowa, February 26, 1898. He received an A.B. degree from the University of South Dakota in 1920 and completed his medical training at Rush Medical College where he received his M.D. in 1923. His internship was served at Cook County Hospital, Chicago. Three months of postgraduate work were spent at the University of Vienna.

Dr. Graves was associated for some seventeen months with Dr. Robert Emmett Farr of Minneapolis and for eighteen months with the Peabody Clinic at Webster, South Dakota.

Dr. Graves was a member of St. Louis County Medical Society, the Minnesota State Medical Association and the American Medical Association. He was a Fellow of the American College of Surgeons, the Interurban Academy of Medicine and the Duluth Surgical Society.

Dr. Graves was a veteran of both World War I and World War II, having served in the U. S. Navy.

He is survived by his parents, his wife and two children.

A. D. HASKELL

Dr. A. D. Haskell, well known physician of Alexandria for the past four decades, passed away December 2, 1951, at the age of seventy-four.

Dr. Haskell was born at Anoka, Minnesota, May 16, 1877. He obtained his M.D. degree from the University of Minnesota in 1900 and interned at the City and County Hospital (now the Ancker) in Saint Paul. He practiced at Carlos, Minnesota, from 1900 to 1910.

Married in Minneapolis in 1907, Dr. and Mrs. Haskell moved to Alexandria in 1910.

Always active in community affairs, Dr. Haskell served as mayor in 1937 and as a member of the city council and board of public works during his residency in Alexandria. He was president of the Park Region Medical Society in 1928 and was a member of the Minnesota State Medical Association and the American Medical Association.

Dr. Haskell is survived by his wife.

RUSSELL ROBERT HENDRICKSON

Dr. R. R. Hendrickson of Crookston died December 18, 1951, at the age of forty-eight.

Dr. Hendrickson was born at Iron River, Wisconsin, August 17, 1903. He attended Eveleth High School and Eveleth Junior College. He obtained an M.D. degree at the University of Minnesota in December, 1927, and interned at St. Mary's Hospital, Duluth.

At one time Dr. Hendrickson served as medical officer for the St. Cloud reformatory. He practiced at St. Cloud from 1930 to 1938. He was at one time superintendent and medical director of Buena Vista Sanatorium at Wabasha, superintendent of Fair Oaks Lodge sanatorium at Wadena and of Sand Beach Sanatorium at Lake Park, near Detroit Lakes. During World War II, he was tuberculosis specialist for the U. S. Public Health Service in Alaska and served as chief of the tuberculosis service at the Marine Corps hospital in New York. He was medical director and superintendent of Sunny Rest Sanatorium at Crookston for nine months before his enforced retirement because of a heart ailment.

Dr. Hendrickson is survived by his wife, two sons, Russell J., and Jack, and a daughter, Mary Katherine.

OLAF KITTLESON

Dr. Olaf Kittleson, a native of Zumbrota township, Minnesota, died December 5, 1951, at Willmar, Minnesota, where he was a member of the medical staff at the State Hospital. He was sixty-four years of age, having been born July 13, 1887.

He attended the high school at Zumbrota and graduated from the University of Minnesota medical school in 1912. He was a fellow at the Mayo Clinic for two years and later served in World War I for three years.

Dr. Kittleson practiced medicine in Minneapolis and in Zumbrota before accepting a position at the Willmar State Hospital in February, 1951. He had never married.

THURSTON WILLIAM WEUM

Dr. Thurston William Weum, a specialist in obstetrics and gynecology in Minneapolis for more than thirty years, died on December 20, 1951, at the age of sixty-nine, after a long illness.

Dr. Weum was born in 1882 at Norcross, Minnesota, and attended school at Moorhead. He attended the University of Minnesota and the University of Chicago before obtaining an M.D. degree at Northwestern University.

He practiced medicine at Duluth and at South Haven, Minnesota, before locating in Minneapolis.

Dr. Weum was a diplomate of the American Board of Obstetrics and Gynecology and a fellow of the American College of Surgery. He was also a member of the Central Association of Obstetrics and Gynecology, the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association. He had been on the faculty of the Medical School of the University of Minnesota since 1918.

Dr. Weum is survived by his wife, Evelyn, and two daughters, Mrs. Marjorie Yench of New York and Audrey Weum of Milwaukee.

Of General Interest

In the Third Supplement of the United States Pharmacopoeia XIV, the definition of Liver Injection is changed to read:

> "Liver injection is a sterile solution in water for injection of that soluble thermostable fraction of mammalian livers which increases the number of red corpuscles in the blood of persons affected with pernicious anemia. Each cubic centimeter of Liver Injection has a vitamin B_{12} activity equivalent to either 10 or 20 micrograms of cyanocobalamin. The potency is not less than 100 per cent and not more than 150 per cent of that stated on the label.
>
> "Liver injection may contain not more than 0.5 per cent of cresol or of phenol as a bacteriostatic agent."

Thus, liver injection in the future will be standardized so that the activity of one unit corresponds to that of one microgram of B_{12}. This change became official on January 1, 1952. Official preparations will have an activity of 10 or 20 micrograms per cubic centimeter.

* * *

Dr. Robert E. Gross, Ladd Professor of Children's Surgery at Harvard Medical School, will present the George E. Fahr lecture on "Coarctation of the Aorta" on April 8 at 8:15 p.m., at the ampitheater, Owre Hall (formerly Medical Sciences) at the University of Minnesota.

* * *

Dr. Marie K. Bepko, Cloquet, attended the third Congress of the Pan-American Medical Women's Alliance, Inc., at Montevideo, Uruguay, from December 2 to 8. The meeting was held in conjunction with the Pan-American Pediatric Society and the South American Pediatric Society. Tied in with the meeting was a tour which included visits to Rio de Janeiro, Buenos Aires, Santiago and Lima in South America and Port-of-Spain and San Juan, Puerto Rico. Dr. Bepko was away from Cloquet for about a month while on the tour.

* * *

Dr. Robert E. Priest and **Dr. William J. Kucera, Jr.,** are now associated at 302 Medical Arts Building, Minneapolis, in the practice of otolaryngology, laryngeal surgery and broncho-esophagology. Dr. Kucera, a graduate of the University of Minnesota Medical School, completed a three-year fellowship in otolaryngology at the University of Illinois on July 1, 1951. He is the son of **Dr. William J. Kucera, Sr.,** of Minneapolis.

* * *

After serving on the board of education at Wadena for eighteen years, **Dr. John S. Grogan** of Wadena resigned early in December. He stated that because of his duties with the Red Cross blood mobile unit he was unable to attend board meetings. During his years of service on the board Dr. Grogan was very active in developing school athletic facilities in Wadena.

Dr. Ralph T. Knight, Minneapolis, was elected president-elect of the American Society of Anesthesiologists at the annual meeting held at Washington, D. C., in November. Dr. Knight is a member at present of the board of directors and of the executive committee and will take office as president in November, 1952.

* * *

G. Ray Higgins, former director of students' unions at the University of Minnesota, was recently appointed executive secretary of the **Minnesota Heart Association.** Mr. Higgins has been director of students' unions for the past ten years.

* * *

It was announced on December 12 that **Captain Alexander M. Boysen,** a former Minnesota physician, had been listed by the Peking, China, radio, in a propaganda broadcast about treatment of prisoners, as being among the United States prisoners of war in Korea. Dr. Boysen was reported on July 12, 1950, as missing in action, and a few weeks later it was first reported that he was a prisoner of war. Minnesota Medicine has not yet heard whether his name was on the "official" lists released by the Reds later last month.

* * *

Dr. and Mrs. R. P. Michels, Willmar, returned home on December 6 from Chicago, where Dr. Michels took a week of postgraduate study.

* * *

Minnesota Blue Cross—Blue Shield is sponsoring Cedric Adams' "Dinner at the Adams'" half-hour radio show every Friday night from 7:00 to 7:30 p.m. over the WCCO-CBS station. This is the strongest and most influential station in the Northwest and will transmit information regarding these voluntary hospital and medical plans throughout the state.

* * *

Dr. Jan H. Tillisch, Rochester, has been appointed medical adviser to Mid-Continent Airlines. He has been a director of the company since 1949.

* * *

Dr. Allan J. Blake, Hopkins, has resigned as physician for the county home school for boys due to the demands of his private practice. He held the school post for the past two years.

* * *

The annual Phi Delta Epsilon lectureship at the University of Minnesota will be given in the auditorium of the University's Museum of Natural History at 8:15 p.m. on February 14. **Dr. Charles P. Bailey,** Philadelphia, will discuss "Recent Advances and Future Trends in Cardiac Surgery." All physicians and medical students are invited to attend.

* * *

Dr. Albert V. Stoesser and **Dr. Lloyd S. Nelson,** Minneapolis, have moved their offices from 1409 Willow Street to the LaSalle Building (Suite 616), located at Seventh Street and Marquette Avenue, Minneapolis. Their practice is limited to pediatrics and allergy.

* * *

It was announced in November that **Dr. Bernard S. Nauth**, Bagley, had resumed his practice at the Clearwater Clinic following a two-month absence. He is associated in practice with Dr. L. J. Larson.

* * *

Kenny Therapists.—Fifteen registered nurses and physical therapists from seven states and two foreign countries were awarded certificates as graduate Kenny therapists in the treatment of infantile paralysis in ceremonies at Westminster Presbyterian Church, Minneapolis, on December 19.

They were from a group of forty-eight trainees, the largest class to be in training as student Kenny therapists since the Kenny Institute, the Kenny Foundation's international Kenny therapist training center, was opened in Minneapolis in 1942. Thirty-three students are still in various phases of their training.

Designed to qualify trainees to become Kenny therapists, a new twenty-four-month course will be opened to registered nurses and physical therapists at Kenny Institute in June. Application blanks for Kenny therapist training scholarships for nurses and physical therapists are available by writing to the Director of Training, Sister Elizabeth Kenny Foundation, 1800 Chicago Avenue, Minneapolis, Minnesota.

Marvin L. Kline, executive director of the Kenny Foundation, was principal speaker at commencement exercises for the 1951 class. Dr. Miland E. Knapp, chief of physical medicine in charge of therapist training for the foundation, presented the certificates.

The training of Kenny therapists consists of an intensive course in the Kenny concept and treatment of poliomyelitis. This specialized training is supplemented by courses in anatomy and physiology at the University of Minnesota Medical School. Students serve through two periods of polio incidence during their training course, which includes classroom instruction and work with polio patients. Before receiving a certificate, the trainee is given an opportunity to demonstrate ability to manage polio cases from admission to final discharge. Upon graduation, new fully-qualified Kenny therapists are assigned to one of the Kenny facilities in this country.

to the Hennepin County Medical Society in Minneapolis on January 4. The title of her talk was "Impressions of Great Britain."

* * *

Principal speaker at the first annual meeting of the nurses of Stearns County, held at Melrose on December 10, was **Dr. Robert N. Barr,** deputy executive officer of the Minnesota Department of Health. He discussed the advances made in fighting communicable diseases and described the problems now involved in diseases of the older age groups.

* * *

Dr. and Mrs. Charles H. Slocumb returned home to Rochester on November 14 after a two and one-half month trip to Europe. During the trip Dr. Slocumb, who is a consultant in the section on rheumatology at the Mayo Clinic and president of the American Rheumatology Association, spoke at several medical meetings and visited numerous hospitals.

* * *

On December 14 the board of regents of the University of Minnesota approved the appointment of **Dr. Robert B. Howard** as director of continuation medical education. Dr. Howard succeeds **Dr. George Aagaard,** who resigned on December 31 and became dean of Southwestern Medical School at the University of Texas.

Dr. J. D. Van Valkenburg was honored at a farewell party given by residents of Floodwood on December 30. Called back to service, Dr. Van Valkenburg left Floodwood on January 5 to become a major in the Air Force. He first began practice at Floodwood in 1936 and was there continuously, with the exception of four years which he spent in service during World War II.

* * *

At the annual staff meeting of the Mayo Clinic in Rochester on November 19, **Dr. J. W. Kernohan** was elected staff president, succeeding **Dr. Paul A. O'Leary.** Named as vice president was **Dr. L. T. Austin,** while **Dr. M. B. Coventry** was re-elected secretary.

The staff also approved a reorganization plan enlarging the clinic board of governors from nine to eleven members. The board was enlarged, it was said, to facilitate the handling of administrative problems of the steadily growing clinic. One of the new members named to the board is a physician, **Dr. M. W. Comfort,** a consultant in internal medicine at the clinic.

* * *

Dr. Roger L. J. Kennedy, Rochester, spoke on "Catholic Action" at a meeting of the Queen of Angels Holy Name Society in Rochester on December 9. Dr. Kennedy was recently honored by

Pope Pius XII and given the title of Knight of St. Gregory for his religious and civic activities.

* * *

Dr. Hamlin Mattson, Minneapolis, has been invited by the board of the Swedish Surgical Society to present a paper on the surgery of inguinal hernia at a meeting of the society in Malmo-Lund, Sweden, April 25 and 26.

* * *

Dr. John F. Madden, Saint Paul, was recently elected to the board of directors of the American Academy of Dermatology and Syphilology.

* * *

Dr. Robert B. J. Schoch, Saint Paul city health officer, has been made a fellow of the American Public Health Association. The fellowship is bestowed for outstanding public health work. Dr. Schoch has held his present position in Saint Paul for seventeen years.

* * *

Dr. Jack Heimark, son of **Dr. and Mrs. J. J. Heimark** of Fairmont, has been awarded a three-year fellowship in internal medicine at the Mayo Foundation, Rochester. He is a recent graduate of the University of Minnesota Medical School.

* * *

Guest speaker at a meeting of the Quality Club and the ReVera Club at Redwood Falls on November 19 was **Dr. P. B. Grimes,** superintendent of the St. Peter State Hospital, who described the care given patients and discussed needed improvements.

* * *

Dr. Stanley V. Lofsness, Minneapolis, has joined the associate medical and surgical staff of St. Lucas Hospital at Faribault as consultant pathologist. He will be at the hospital on a part-time basis and will conduct regular clinical-pathological conferences for the staff members. Dr. Lofsness is also associated with the Pathology Department of the University of Minnesota Medical School.

* * *

Dr. Francis G. Blake, wartime advisor to the President on problems of epidemic disease and former dean of the Yale Medical School, has been named civilian technical director of medical research in the office of the Army Surgeon General.

Dr. Blake will serve as expert consultant to Colonel John R. Wood, M.C., chairman of the Army Medical Research and Development Board, in the evaluation of current and proposed research projects conducted by Army medical installations and eighty-one co-operating civilian institutions. He will be responsible for ensuring close co-ordination between the Army's present $10,079,000 medical research effort and similar programs sponsored by the other armed forces and civilian Federal agencies.

Dr. Blake is sixty-four years of age, a graduate of Dartmouth College and Harvard Medical School. He interned at Peter Bent Brigham Hospital in Boston and in 1917 was appointed assistant professor of medicine at the University of Minnesota.

* * *

It was announced during the middle of December that **Dr. Norman J. Lee,** Saint Paul, would become associated in practice with **Dr. W. G. Workman** at Tracy shortly after the first of the year.

* * *

Dr. M. J. McMahon, after twenty-five years of practice at Green Isle, has accepted a position on the medical staff of the St. Cloud Veterans Hospital.

* * *

New officers of the Minnesota and the Minneapolis chapters of the American Academy of General Practice have been announced. For the state chapter they are **Dr. James A. Blake,** Hopkins, president; **Dr. Willis L. Herbert,** vice president, and **Dr. Alexander J. Ross,** secretary-treasurer, both of Minneapolis.

Officers of the Minneapolis chapter are **Dr. Herman E. Drill,** Hopkins, re-elected president; **Dr. E. G. Oppen,** Minneapolis, re-elected vice president, and **Dr. Louis J. Roberts,** secretary-treasurer.

* * *

Open house was held on December 13 at a newly constructed clinic in Dawson, staffed by **Dr. Vilhelm M. Johnson** and **Dr. George Boody.** The one-story, modern designed building is divided into three suites for doctors, with additional rooms for x-ray, emergency surgery, laboratory and business office.

ANNUAL CLINICAL CONFERENCE

CHICAGO MEDICAL SOCIETY

March 4, 5, 6, 7, 1952 • Palmer House, Chicago

Special Feature of the 1952 Conference—DAILY TEACHING DEMONSTRATIONS

Thirty-four outstanding teachers and speakers will present half-hour lectures on subjects of interest to both general practitioner and specialist.

FOUR PANELS ON TIMELY TOPICS.

Scientific Exhibits worthy of real study and helpful and time-saving technical exhibits.

The CHICAGO MEDICAL SOCIETY ANNUAL CLINICAL CONFERENCE should be a MUST on the calendar of every physician. Plan now to attend and make your reservation at the Palmer House.

Appointments to state boards were announced on December 31. Named a member of the Minnesota State Board of Health was **Dr. F. W. Behmler,** Morris, for a three-year term. **Dr. J. A. Bargen,** Rochester, was appointed to the Minnesota State Board of Medical Examiners to succeed the late Dr. A. W. Adson.

* * *

Special citations from the regents of the University of Minnesota were presented to two 1950 Nobel Prize winners, **Dr. Edward C. Kendall** and **Dr. Philip S. Hench,** both of Rochester, at a dinner at the University on November 29. Speakers at the ceremonies for the men who developed cortisone included President J. M. Morrill of the University and **Dr. Owen H. Wangensteen,** head of the Department of Surgery at the University.

HOSPITAL NEWS

Listed below are the results of recent staff elections at various Minnesota hospitals:

Blue Earth Community Hospital, Blue Earth.—Dr. H. H. Russ, chief-of-staff; Dr. G. W. Drexler, secretary-treasurer.

St. Luke's Hospital, Saint Paul.—Dr. Donald C. Deters, chief-of-staff; Dr. Walter T. Brodie, vice chief-of-staff; Dr. John Farkas, secretary.

St. Cloud Hospital, St. Cloud.—Dr. F. H. Baumgartner, chief-of-staff; Dr. John F. Kelly, vice president; Dr. R. T. Petersen, secretary.

Asbury Methodist Hospital, Minneapolis.—Dr. Harold F. Wahlquist, president; Dr. Wayne H. Hagen, vice president; Dr. Karl D. A. Andresen, secretary-treasurer.

County Hospital, Olivia.—Dr. Chester A. Anderson, president and chief-of-staff; Dr. H. P. Hinderaker, vice president; Dr. M. B. Dahle, secretary-treasurer.

St. John's Hospital, Saint Paul.—Dr. C. Kenneth Cook, president; Dr. T. S. McClanahan, vice president; Dr. C. R. Tifft, second vice president; Dr. F. J. Milnar, secretary.

* * *

It was announced on December 20 that Dr. William C. Heiam is adding another addition to the **Cook General Hospital** at Cook. There will be space for five more beds and a children's room.

* * *

Two new laboratories—a $180,000 installation—were opened at **Minneapolis Veterans Hospital** on December 12. One is a radioisotope laboratory and the other a surgical research laboratory. The research work being done in these new laboratories, together with the numerous other projects being conducted at the hospital, makes the Minneapolis Veterans Hospital the third largest research center in Minnesota.

* * *

The new superintendent of **Minneapolis General Hospital** is Kenneth Holmquist, former assistant superintendent at the University of Minnesota Hospitals. Mr. Holmquist is the first non-medical man to hold the post in the hospital's sixty-four years. He succeeded the late Dr. D. W. Pollard.

Although Mr. Holmquist is administrative head of the hospital, the medical staff has its own chief for professional decisions, Dr. Thomas Lowry. Shortly after taking over, Mr. Holmquist started the policy of holding administrative staff meetings each month, corresponding to the medical staff meetings, which he also attends.

BLUE CROSS-BLUE SHIELD

The Minnesota Blue Shield contract covering U. S. Steel employes which became effective August 1, 1951, contains uniform benefits throughout the nation for subscribers covered by this special contract, and therefore it was necessary to issue a separate schedule of payments to doctors which is titled "Schedule of Payments to Doctors of Medicine for Surgical and Obstetrical Group Contract S-1." The insert in this schedule lists the subsidiary companies affected by this schedule. On October 8, 1951, letters were sent to each participating doctor in Minnesota informing him of this new U. S. Steel schedule which was available upon request to this office. In this letter it was pointed out that most persons covered under this contract live in Duluth or on the Iron Range. In response to this letter, a rather general distribution of this schedule was made, as requested by the doctors or clinics.

During the interval since the effective date of the U. S. Steel contract, it appears that in some instances the doctor or his office assistant is under the impression that the schedule of payments to doctors for U. S. Steel employes replaced the standard "Schedule of Payments to Doctors of Medicine, M.S. 1-5-51." However, the standard schedule as revised May 1, 1951, still determines the amounts paid on all Blue Shield contracts except those subscribers covered under the Steel contract.

The allowances in the Steel contract are somewhat higher for some procedures. Under the Steel schedule some surgical items carry a payment of $200.00 and obstetrical deliveries carry a $60.00 payment. It should be pointed out that only surgical and obstetrical services are payable under the Steel contract. No allowances are included for medical care in the hospital, the home or the office, and further, ancillary services including x-rays, anesthesia and some endoscopic examinations are ineligible for payment as claims. The Steel Contract is not a service but a straight indemnity contract. The payments made by Blue Shield under this contract apply on the doctor's bill but are not necessarily full payment.

October, 1951, was the first month of Minnesota Blue Shield's four years of experience in which over 10,000 claims were processed. This October claim load of 10,348 represents a 60 per cent increase over the 6,009 claims processed in October of 1950. Of further interest in this regard is a comparison of subscriber enrollment in October of each year. In 1950, there were 385,512 subscribers while in October, 1951, there were 515,442 subscribers, an increase of approximately 7.5 per cent. Quite clearly this indicates a sharp increase in the number of claims per thousand contracts.

These claims and enrollment figures are given further emphasis by the cost of claims processed this year as compared with 1950. During October just passed, incurred claims cost amounted to $323,208, whereas claims paid in October, 1950, amounted to $227,729. Also the cost of claims paid during the first ten months of 1950 amounted to $1,781,545, while claims cost for the same period of 1951 was $2,567,017.

Blue Cross payment to hospitals for October was $982,018, and to date this year $9,399,204, compared with $8,165,879 to date last year. During October, 10,141 participant subscribers were enrolled in Blue Cross bringing the total enrollment as of October 31, 1951, to 1,020,806.

Blue Cross and Blue Shield Sponsors Cedric Adams

For some time Minnesota Blue Cross and Blue Shield Plans have felt the need of a broader and more personal contact with the general public. The need for better public relations and understanding of the part we play in our statewide community is genuinely felt, and because of the great pulling power of Cedric Adams, experienced during the past non-group campaigns we are now sponsoring Cedric Adams' own show, "Dinner at the Adams."

Without doubt Cedric Adams is the most highly regarded and universally admired radio personality in the Northwest. "Dinner at the Adams" is a half-hour program broadcast over WCCO-CBS every Friday night at

The Birches Sanitarium, Inc.

2391 Woodland Avenue
Duluth 3, Minnesota

A hospital for the care and treatment of Nervous and Mental disorders. Quiet, cheerful environment. Specially trained personnel. Recreational and occupational therapy.

Dr. L. R. Gowan, M.D., M.S., Medical Director

7:00-7:30 p.m. On the program each week will be well-known, exciting and interesting personalities as personal dinner guests of the Adams family, and their weekly discussions will cover a wide range of sparkling and timely subjects. The "Dinner at the Adams" show is a genuinely wholesome and family type of entertainment with a tremendous listener appeal to young and old in every walk of life.

New Farm Bureau $25 Deductible Blue Cross Contract

As of January 1, 1952, a $25 deductible clause will be attached to all Farm Bureau Blue Cross group contracts. Blue Cross has developed this $25 deductible contract offering all Farm Bureau subscribers the most amount of benefits for a minimum rate, and yet maintaining the catastrophic coverage that Blue Cross has always given.

The fact that farmers and their families have used 110 per cent more Blue Cross benefits than they paid for accentuated the need of a $25 deductible contract.

The $25 deductible Blue Cross contract specifically geared to the needs of Farm Bureau members was adopted after careful study by Minnesota Blue Cross and the Farm Bureau Federation board members who long have been seeking a satisfactory answer to the task of giving farm bureau subscribers the most protection at a minimum rate.

The $25 deductible feature for all Farm Bureau subscribers and their dependents will permit Blue Cross to offer seven dollars a day for room, board, and general nursing allowance in place of $5 included under the present contract offered most Farm Bureau members, plus full and complete service benefits for ancillary services included in the contract at no increase in rates.

When the Farm Bureau subscriber or one of his dependents is hospitalized, he will not be covered for the first $25 of hospitalization. It is the subscriber's responsibility to meet his own hospital bill when the charge is twenty-five dollars or less. The $25 deductible contract gives the Farm Bureau subscribers an opportunity to meet their own hospitalization when the cost is minor, and keeps intact the farmer's right to real protection when the hospital bill is catastrophic.

AIDS TO COMMUNITY HEALTH PLANNING

To help communities start new health councils—or make existing councils better—the National Health Council has prepared a new "loan kit" of health promotion literature. The kit, entitled "Aids to Community Health Planning," may be borrowed for a month at a time, with privilege of renewal, or purchased for $2.50.

A health council is a planning and co-ordinating body of voluntary health groups, professional societies, official agencies and citizens' groups working together for community health. There are thirty-two state and 1,200 local councils in the country today, the National Health Council reports.

Divided into six sections, the kit contains more than a score of pamphlets, leaflets and reprints for the use of individuals and groups seeking to improve their community's health programs.

The material covers programs, activities, structure and financing of health councils. It includes sample constitutions and by-laws both for rural and urban councils and for health divisions of welfare councils.

For loan or purchase, write: National Health Council, 1790 Broadway, New York 19, New York.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

PATHOLOGY OF THE FETUS AND THE NEWBORN. Edith L. Potter, M.D., Ph.D. Associate Professor of Pathology, Department of Obstetrics and Gynecology, University of Chicago; Pathologist, Chicago Lying-in Hospital; Chief Pathologist, Chicago Department of Health. 574 pages. Illus. Price $19.00, cloth. Chicago: Year Book Publishers, Inc., 1952.

PLASTIC SURGERY OF THE NOSE. James Barrett Brown, M.D. Professor of Clinical Surgery, Washington University School of Medicine, St. Louis, Missouri; Chief Consultant in Plastic Surgery, United States Veterans Administration, Washington, D. C.; formerly Senior Consultant in Plastic Surgery, U. S. Army and in E.T.O., and Chief of Plastic Surgery, Valley Forge General Hospital; and Frank McDowell, M.D., Assistant Professor of Clinical Surgery, Washington University School of Medicine, St. Louis, Missouri. 427 pages. Illus. Price $15.00, cloth. St. Louis: C. V. Mosby Co., 1951.

BIOLOGICAL ANTAGONISM—The Theory of Biological Relativity. Gustav J. Martin, Sc.D. Research Director of the National Drug Co., Philadelphia. 516 pages. Illus. Price $8.50, cloth. Philadelphia: The Blakiston Co., 1951.

SURGERY OF THE OBLIQUE MUSCLES OF THE EYE. Walter H. Fink, M.D., Minneapolis. 350 pages. Illus. Price $8.75, cloth. St. Louis: C. V. Mosby Co., 1951.

ANNUAL REPORT ON STRESS. Hans Selye, M.D., Ph.D. (Prague), D.Sc. (McGill), F.R.S. (Canada). Professor and Director of the Institut de Medicine et de Chirurgie experimentales, Universite de Montreal. 511 pages. Illus. Price $10.00, cloth. Montreal, Canada: Acta, Inc., 1951.

THE APHORISMS OF DR. C. H. MAYO AND DR. W. J. MAYO. Collected by Fredrick A. Willius, M.D. 109 pages. Illus. Price $2.75, cloth. Springfield, Illinois: Charles C Thomas, 1951.

ANTIBIOTIC THERAPY. Henry Welch, Ph.D., Director, Division of Antibiotics, Food and Drug Administration, Federal Security Agency of United States Government; and Charles N. Lewis, M.D., Medical Officer, Division of Antibiotics, Food and Drug Administration, Federal Security Agency of United States Government; foreword by Chester S. Keefer, M.D., Wade Professor of Medicine, Boston University School of Medicine, Chairman, Committee on Medicine, and Chairman, Committee on Chemotherapy of the National Research Council. 562 pages. Illus. Price $10.00, cloth. Washington, D. C.; The Arundel Press, 1951.

THE TEMPOROMANDIBULAR JOINT. Bernard G. Sarnat, M.S., M.D., D.D.S., F.A.C.S. Professor and Head of Department of Oral and Maxillofacial Surgery, College of Dentistry, Clinical Assistant Professor, Department of Surgery (Plastic Surgery), College of Medicine, University of Illinois, Chicago; Diplomate of the American Board of Plastic Surgery. 148 pages. Illus. Price $4.75, cloth.

PENICILLIN DECADE, 1941-1951. Lawrence Weld Smith, M.D. Medical Director Commercial Solvents Corporation; and Ann Dolan Walker, R.N., former editor "Trained Nurse and Hospital Review." 122 pages. Price $2.50, cloth. Washington, D. C.: The Arundel Press, 1951.

UNTOWARD REACTIONS OF CORTISONE AND ACTH. Vincent J. Derbes, M.D., F.A.C.P. Associate Professor of Medicine, Tulane University of Louisiana School of Medicine; Head of Department of Allergy, Ochsner Clinic; Visiting Physician Charity Hospital of Louisiana at New Orleans, and Staff Member, Foundation Hospital, New Orleans; and Thomas E. Weiss, M.D., Instructor in Medicine, Tulane University of Louisiana School of Medicine; Member of Department of Medicine, Ochsner Clinic; Visiting Physician Charity Hospital of Louisiana at New Orleans and Staff Member Foundation Hospital, New Orleans. 77 pages. Price $2.25, flexible binding. Springfield, Illinois: Charles C Thomas, 1951.

DIABETES CONTROL. By Edward L. Bortz, M.D., Associate Professor of Medicine, University of Pennsylvania; Past President, American Medical Association. 264 pages. Price $3.50. Philadelphia: Lea and Febiger, 1951.

This is a manual written primarily for the diabetic patient. The first few chapters are devoted to improving morale of the diabetic patient as well as general instructions. The chapter on care of the feet is exceptionally good. A long chapter on meal planning makes use of

REST HOSPITAL

2527 Second Avenue South, Minneapolis

A quiet, ethical hospital with therapeutic facilities for the diagnosis and treatment of nervous and mental disorders. Invites co-operation of all reputable physicians. Electroencephalography available.

PSYCHIATRISTS IN CHARGE
Dr. Hewitt B. Hannah
Dr. Andrew J. Leemhuis.

the food exchange lists as adopted by the Committees of the American Diabetes Association and the American Dietetic Association. This new information gives to the patient a much wider choice of foods and an easier method of computing his diet. This new system has been adopted by the dietetic departments of many hospitals. This chapter alone is worth the price of the book.

The chapter on insulin covers N.P.H. insulin and the new insulin syringes. A chapter on weight control is valuable to the obese, whether diabetic or not.

The last chapter is a list of questions and answers.

It covers all phases of diabetes in simple language printed in easily read type on fine paper.

It is a valuable book for the diabetic patients, especially those who have received instructions from dieticians who are using the new food "exchange" system. It is a worthwhile addition to a physician's library.

Lloyd L. Merriman, M.D.

LOW-SODIUM DIET. A MANUAL FOR THE PATIENT. By Thurman B. Rice, A.M., M.D. Professor of Public Health, Indiana University School of Medicine, Indianapolis, Indiana. 103 Pages, 14 Food Charts. Price $2.75. Philadelphia: Lea & Febiger, 1951.

The low sodium diet, as such, is mighty difficult to follow due to its extreme unpalatability and limitations. As a result, the average person when confronted with the prospect of having to follow this extremely restricted diet many times will think, "Well, what's the use?"

The information which is given in Dr. Rice's book is particularly aimed at the average person with an average amount of knowledge and understanding. He tells why sodium is important in the diet, where it can be found, which foods to eat, and which to omit. There is one chapter on possible ways of varying the diet and relieving the monotony, and the problem of "eating out." He discusses foods that have hidden sodium in them due to processing. There are several chapters on actual samples of low-sodium diets and food charts indicating sodium content, et cetera.

In general, this book can be considered a good valid source of information. It explains in greater detail than the doctor or dietitian can take time to explain the important aspects of this particular modified diet.

Adeline V. Paulson

STANDARD NOMENCLATURE OF DISEASES AND OPERATIONS, Fourth Edition. American Medical Association. 1034 pages. Price $8.00. Philadelphia: Blakiston Co., 1952.

On January 2, 1952, the American Medical Association made available to hospitals the new fourth edition of Standard Nomenclature of Diseases and Operations.

Revision of this useful book has been under way intensively for the past three years starting with the decision to revise made at the Fifth National Conference on Medical Nomenclature held at the Association Headquarters office in June, 1948. Revision of the book was carried out by the editors under the general supervision of an Editorial Advisory Board and in collaboration with twenty-four committees representing each of the individual or specialty sections of the book.

Since its inception under the auspices of the New York Academy of Medicine, and the First National Conference on Medical Nomenclature in 1928, and the subsequent transferral of responsibility for its periodic revision to the American Medical Association in 1937, the "Standard Nomenclature" has grown rapidly to become the standard, and thereby the most acceptable system for the diagnostic coding of hospital records for more than seventy per cent of U. S. Hospitals. Although the dual topographic-etiologic coding system is not uncomplicated, it has many times over demonstrated its flexibility both through ease of simplification for the

INSTRUMENTS · TRUSSES · EQUIPMENT · PHARMACEUTICALS · DRUGS
MAIN 2494

small hospital, and in ready expansibility for the large teaching and research hospital.

Because of the wide acceptance of this coding system, and the fact that hospital record systems using "Standard" must make the changes provided for in each revision, the editors of the Fourth Edition have made every effort to avoid changes that are not strictly required. Nevertheless, the rapidly expanding scientific knowledge in many fields in recent years has required a considerable number of changes in several sections of the book. These have included a complete revision of the Psychobiologic section to bring it into accord with accepted diagnostic terminology of the American Psychiatric Association, a complete revision of the diseases of the Hemic and Lymphatic section to accord with newer thought in this field, and a complete revision of the section on tumor etiology. Changes in the nomenclature and coding of tumors comes about as a result of the deliberations of the "Standard" Committee on Oncology with similar committees of the American Cancer Society, the National Research Council, the U. S. National Committee on Health and Vital Statistics, American Society of Clinical Pathologists, Armed Forces Institute of Pathology, U. S. Public Health Service and others, all of whom have adopted the new nomenclature.

For purposes of a closer identification of two systems, the Fourth Edition of Standard has included an appendix cross reference of "Standard" code numbers to code numbers of the "International Statistical Classification of Diseases, Injuries and Causes of Death." The "International" code numbers have also been included parenthetically in the Nomenclature section of the book. The main purpose of this has been to simplify the work of hospitals who do, or may wish to, participate in or contribute toward large-scale state, nation, or world statistical studies of disease incidence. It must be emphasized, however, that for purposes of hospital recording, the systems are by no means interchangeable. The "Standard" system, as a clinical system, is necessary for the proper separation of individual differences in diseases for recording and research purposes, whereas the "International" system applies mainly to much broader disease groupings for statistical purposes. Thus, one code number in the International list may be used to represent twenty or more conditions classified and coded separately in the "Standard Nomenclature."

In view of the fact that the "International List" is now accepted on a world basis for statistical analyses by the countries participating in the World Health Organization, and the fact that the cross coding to "Standard" has been a tremendously detailed and time-consuming work, it seems pertinent to now suggest that the combined systems, clinical and statistical, may be an appropriate consideration for the World Medical Association for sponsorship or adoption in either the present or next succeeding revision.

Unquestionably, the adoption of "Standard" in the hospitals of this country not now using it can be an effective and needed move toward the unity inherent in calling the same things by the same names.

RICHARD J. PLUNKETT, M.D.

MEDICAL TERMINOLOGY MADE EASY. Je-Harned, R.N., R.R.L., Instructor in Medical Record Library Science and Medical Record Librarian, Duke University School of Medicine and Hospital, Durham, N. C. 275 pages. Price $5.00. Chicago: Physicians' Record Company, 1951.

Written by a person well qualified for the task, this book is primarily an easy-to-read textbook on medical terminology, with special emphasis on the jargon used by physicians and nurses in their speech and in writing hospital records. As the author states, it is not a substitute for a medical dictionary but is intended to introduce beginners in various types of medical work to the specialized language used in the field of medicine. The book is aimed mainly at hospital administrators, pre-

medical and first-year medical students, nurses, medical librarians, technicians, therapists and secretaries.

Every profession or trade, the author points out, has its jargon, which, strange as it may sound to outsiders, is actually, in its own field, "more precise and less liable to errors of interpretation than ordinary English." This, of course, is because a jargon word is coined for a specific thing or act existing or done only under certain circumstances.

In this book, after a general discussion of the subject, the author plunges into an explanation and listing of medical prefixes and pseudo-prefixes, suffixes and pseudo-suffixes, and word stems, in each case giving an example of correct usage. Although etymology can often be dull, except to enthusiasts in the field, the author manages to make these sections of her book not only clear but interesting.

Following this, there is a chapter consisting of selected medical words and phrases (with definitions), based upon the various anatomical systems. Named are the anatomical parts of each system and diseases and pathologic conditions of each system.

The next chapter consists of an alphabetical list of terms commonly used in medical case records. With each word is a brief definition as well as an example of correct usage in a sentence.

There is also an excellent chapter on abbreviations and symbols, which, the author naturally emphasizes, are very important because of the time and space they save in the preparing of medical records and hospital charts. Because of the fact that many abbreviations are purely "local" ones and not in general use, the author divides the abbreviations into three categories and indicates which ones (1) are found in textbooks and dictionaries, (2) are in general use and might be approved in the future, (3) are not approved and are used only in certain locales.

An extremely thorough index completes the book.

All in all, although this book would be of little value to most physicians, it is well suited for those persons (named above) for whom it is intended. In addition, it would make an ideal and practical gift for a physician to present to a son or daughter who is planning to enter either the medical or nursing professions.

METABOLISM

Beginning publication in January, 1952, a new journal will appear bi-monthly under the title of *Metabolism, Clinical and Experimental.* Dr. Samuel Soskin, Director of the Medical Research Institute at the Michael Reese Hospital, Chicago; Dean of the Michael Reese Hospital Postgraduate School, and Associate Professor of Medicine at the Northwestern University Medical School, is Editor-in-Chief. Dr. Fuller Albright, Associate Professor of Medicine at the Harvard Medical School, Boston, has the title of Consulting Editor.

Among the sixteen Associate Editors are Dr. Ancel Keys and Dr. Irvine McQuarrie of the University of Minnesota.

The new journal promises to be rather broad in scope, presenting material both clinical and experimental in nature and providing articles of interest to the general practitioner as well as the specialist and research worker.

Metabolism will contain original articles, abstracts of current literature, editorial discussion, book reviews, clinical reports of a summary or review nature and case reports.

Subscription price is $9.00, payable to the publisher, Grune and Stratton, Inc., 381 Fourth Avenue, New York 16, New York.

DIABETES

A new journal, *Diabetes,* the journal of the American Diabetes Association, will appear bimonthly, beginning with the January-February, 1952, issue. It will be devoted to clinical and research reports on diabetes and related aspects of medicine. It will replace the association's annual proceedings and its quarterly *Diabetes Abstracts,* which have been published for the past ten years.

Diabetes will be edited by Dr. Frank N. Allan of the Lahey Clinic, Boston, with the assistance of an editorial board headed by Dr. Charles H. Best of the University of Toronto.

Members of the association will receive *Diabetes* free. The subscription rate for non-members will be $9 per year. The editorial office is Diabetes, American Diabetes Association, Inc., 11 W. 42nd Street, New York 18, N. Y.

Terramycin

intravenous

Indicated for use in all infections of such severity that intravenous injection is the preferred route, Crystalline Terramycin Hydrochloride Intravenous provides a rapid acting form for the attainment of immediate high serum concentrations. Recommended when oral therapy is not feasible, in severe fulminating or necrotizing infections, in surgical prophylaxis in selected cases, and in peritonitis. For hospital use only.

Supplied | *10 cc. vial, 250 mg.;*
20 cc. vial, 500 mg.

Terramycin is also available as *Capsules, Elixir, Oral Drops, Ophthalmic Ointment, Ophthalmic Solution.*

ANTIBIOTIC DIVISION *Pfizer* **CHAS. PFIZER & CO., INC.,** *Brooklyn 6, N. Y.*

control companion to ACTH and CORTISONE

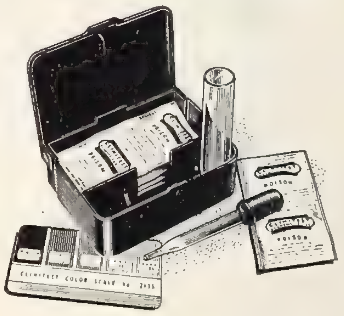
> "In clinical practice it is clearly wise to test the urine of both diabetic and non-diabetic patients for sugar at intervals during administration of cortisone or ACTH and to carry out appropriate investigations and treatment if glycosuria occurs. Particular caution is necessary for diabetic patients."
>
> Sprague, R. G.: Cortisone and ACTH, Am. J. Med. *10*:567, 1951.

To avoid such clinical surprises and simplify clinical control, ACTH and cortisone therapy is profitably *preceded, accompanied* and *followed* by routine testing for urine-sugar. *Clinitest* Reagent Tablets provide a rapid, reliable and convenient method—easily used by both physician and patient.

CLINITEST *for detection of urine-sugar*

BRAND • REG. U. S. PAT. OFF.

REAGENT TABLETS



You can assure regular, reliable urine-sugar analyses by prescribing the Universal Model Set (No. 2155). Available at all pharmacies at $1.50.

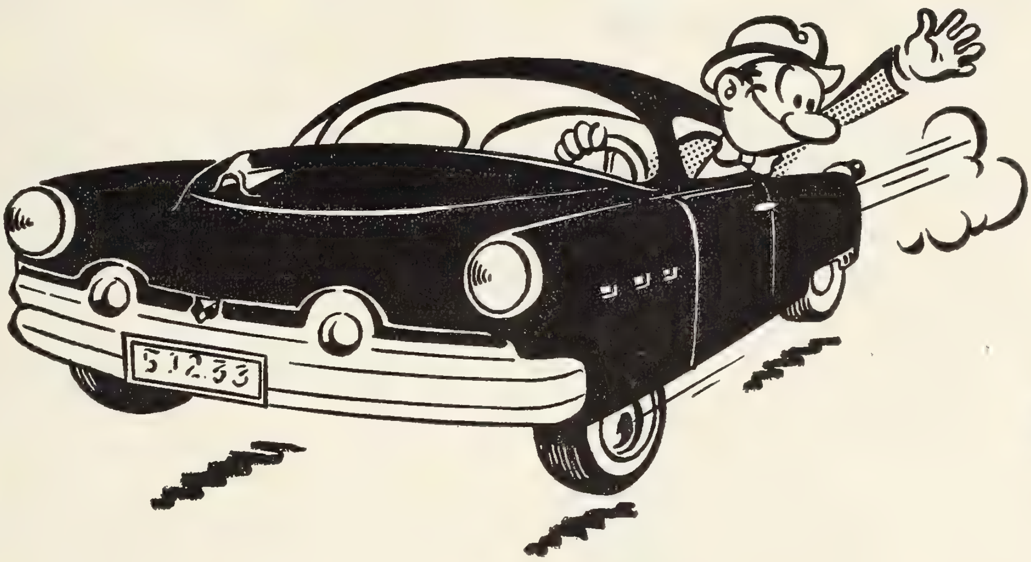
Joe's Sportin' A New Car



On Your Money!

That past due account Joe Doakes owes you puts you in the position of furnishing the cash for Joe's new car. Yes, sir, he's operating on your capital . . . capital that you could nicely use in your own affairs. All those people whose accounts are past due are doing the same thing. Can you afford to run a free bank for them?

YES, SOMETHING CAN BE DONE ABOUT IT!

The I. C. System of Credit and Collection service offered by your Professional Credit Protective Bureau is the answer to your delinquent accounts receivable.

Not A Collection Agency—All Monies Paid Directly to You

COSTS less than collection through your own efforts and in most cases one-half of the usual collection agency fees. Operates with extreme courtesy and goes to the fullest extent the law permits.

PROFESSIONAL CREDIT PROTECTIVE BUREAU
DIVISION OF I. C. SYSTEM
724 Metropolitan Bldg., Minneapolis, Minn.

Professional Credit Protective Bureau

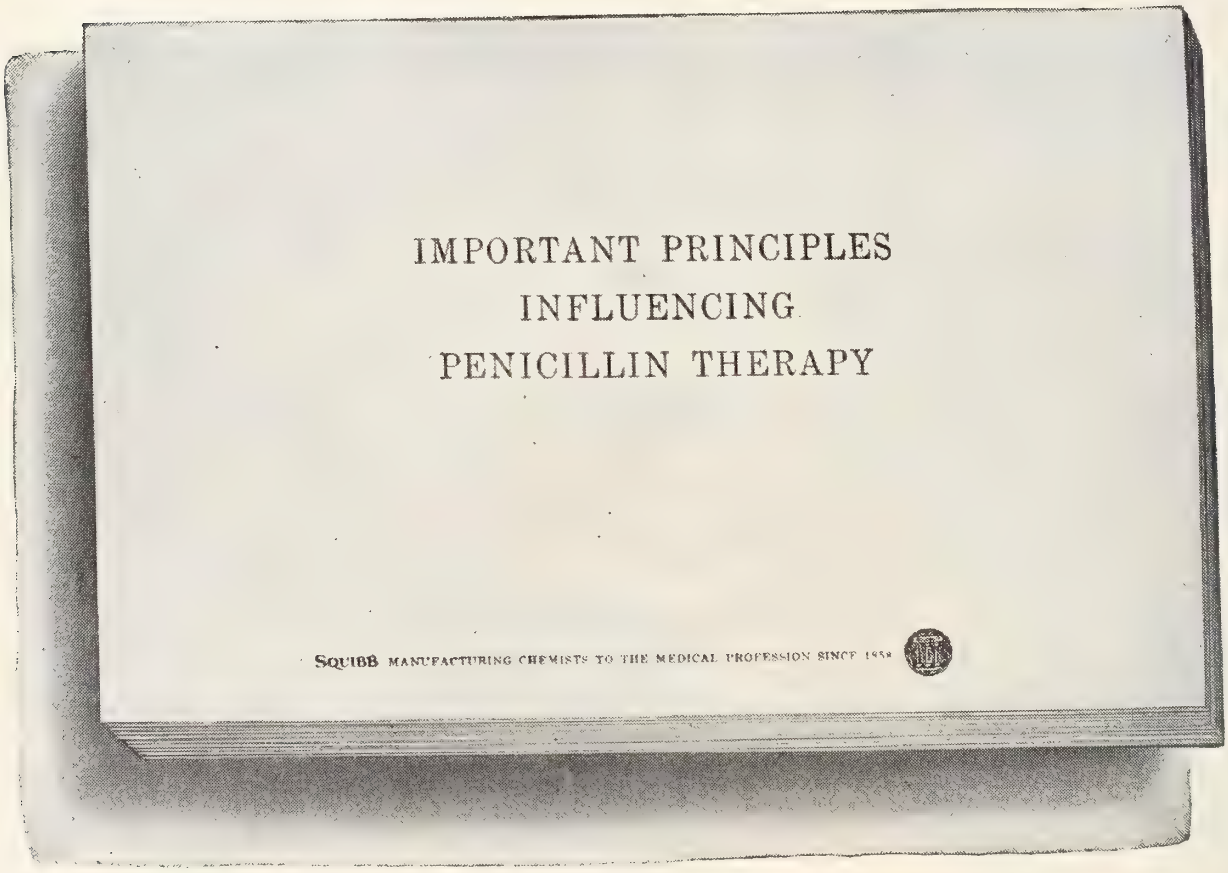
Latest Information on Penicillin Therapy



IMPORTANT PRINCIPLES
INFLUENCING
PENICILLIN THERAPY
SQUIBB MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858

Ask Your Squibb Professional Service Representative

. . . A New Squibb Aid for the Profession

Squibb, a leader in penicillin research and manufacture, presents the new edition of the Squibb Penicillin Handbook, "Important Principles Influencing Penicillin Therapy." It is based on most recent clinical work and data of eminent authorities in the antibiotic field . . . new penicillin dosages . . . new recommendations for efficacy . . . oral and parenteral forms . . . combined therapy . . . drug resistance . . . therapeutic blood levels . . . reactions . . . continuous vs. discontinuous therapy . . . and many other subjects of interest to physicians.

Your Squibb Professional Service Representative will provide you with "Important Principles Influencing Penicillin Therapy" or any other Squibb visual and practical aids, without cost or obligation. Or you may write direct to E. R. Squibb & Sons, 745 Fifth Avenue, New York 22, New York.

SQUIBB A LEADER IN PENICILLIN RESEARCH AND MANUFACTURE

Presenting

The Continental Professional Plan

OF ACCIDENT & SICKNESS INSURANCE

EFFECTIVE and OPERATING FOR

Members of your State

MEDICAL PROFESSION

DESIGNED EXCLUSIVELY
By CONTINENTAL CASUALTY COMPANY
One of the Oldest and Largest Stock Casualty
Companies in the World

A Few of the Many Outstanding Features

- ★ Monthly benefits for both accident and sickness payable FROM FIRST DAY — Minimum claim 7 days.
- ★ Pays monthly benefits for disability resulting from "accidental bodily injury": —the term "accidental means" is NOT used.
- ★ Pays monthly accident benefits regardless of whether disability commences within a certain specified time.
- ★ No automatic termination age.
- ★ The premium does not increase as you grow older.
- ★ House confinement is never required to collect full benefits.
- ★ Indemnities cannot be prorated because of other insurance or for performing duties of a more hazardous occupation.
- ★ Policies cannot be restricted by rider to exclude any disease or injury originating after date of issue.

Renewal is guaranteed to individual active members of the profession regardless of age, so long as the premiums are paid in accordance with the terms of the contract and the plan continues in effect for the members in your designated territory.

The Continental Casualty Company pioneered in the writing of Professional Association Insurance plans. The first such plan, written in 1923, is still in effect and the Company has never cancelled or declined to renew a Professional Plan because of unfavorable loss experience.

NOW available to all eligible members in active practice and under 69 years of age.
Plans A or B available to female members under age 65.

SICKNESS BENEFITS		PLAN AA	PLAN A	PLAN B
PAYS..	A Monthly Indemnity for total disability during first year, whether house confined or not, ...From First Day	$ 300.	$ 200.	$ 100.
PAYS..	Total Monthly Indemnity First 2 Years...	5400.	3600.	1800.
ACCIDENT BENEFITS				
PAYS..	A Monthly Indemnity for total disability during first year ....From First Day	300.	200.	100.
PAYS..	Total Monthly Indemnity First 2 Years...	5400.	3600.	1800.
PAYS..	Monthly Indemnity for partial disability up to 13 weeks ....From First Day	120.	80.	40.

The Cost is Low

	PLAN AA	PLAN A	PLAN B
Annual	$138.00	$92.00	$46.00
Semi-Annual	69.50	46.50	23.50

ADD $5.00 TO FIRST PREMIUM ONLY

OPTIONAL BENEFITS	PLAN AA	PLAN A	PLAN B
Monthly Hospital Indemnity may be added up to ..... for $6.00 per $100 .... Hospital Benefits payable for One to 90 days — Each disability.	$ 450.	$ 300.	$ 150.
Accidental Death and Dismemberment Indemnity up to.. Added for $2.00 per $1000.	7500.	5000.	2500.

THE UPJOHN COMPANY, KALAMAZOO MICHIGAN

"Conforming to the pattern of human milk"

Bremil®

for normal infant development

Clinical experience with thousands of infants demonstrates impressively the valuable role of Bremil in infant nutrition.

Bremil is a completely modified milk in which nutritionally essential elements of cow's milk have been adjusted in order to supply the nutritional requirements of infants deprived of human milk. It can be used with confidence either as part or all of the food supplied to the normal healthy infant.

Bremil conforms to the fatty acid and amino acid patterns of human milk. Bremil is a completely modified milk in which the calcium-phosphorus ratio (guaranteed minimum 1½:1) is adjusted to the pattern of human milk, thus helping to prevent tetanic symptoms in newborns.[1,2]

Bremil supplies the same carbohydrate as breast milk, lactose.[3]

Bremil's vitamin adjustments for standards of infant nutrition,[4] its human-milk size particle curd, miscibility and palatability are additional reasons for its choice in infant feeding. Bremil approximates the nutritional role of the mother.

Available in drugstores in 1 lb. cans.

GREATER BILE VOLUME

ACCEPTED COUNCIL ON PHARMACY AND CHEMISTRY AMERICAN MEDICAL ASSOCIATION

In biliary dysfunction, where copious flow of thin bile is the chief aim of therapy, the physician can place complete reliance upon DEHYDROCHOLIC ACID — Breon and SODIUM DEHYDROCHOLATE — Breon.

Because they are the least toxic of all bile acids and their salts, these products may be employed in full dosage to exert maximum therapeutic effect.

For most efficient drainage of the biliary tract these Breon preparations are indicated in chronic cholecystitis, noncalculous cholangitis, and other biliary disorders where no total obstruction is present.

In your management of biliary patients, specify "Breon" products for purity, pharmaceutical elegance, and uniform end results.

For Oral Administration Tablets — 0.25 Gm. each	**DEHYDROCHOLIC ACID — Breon** Bottles of 100, 500 and 1000 Tablets
For Parenteral Administration 20% w/v Solution	**SODIUM DEHYDROCHOLATE — Breon** 5 cc. Ampuls — boxes of 6 and 25

"Premarin"—a naturally occurring conjugated estrogen which has long been a choice of physicians treating the climacteric—is earning further clinical acclaim in the treatment of functional uterine bleeding.

The aim of estrogenic therapy in functional uterine bleeding is to bring about cessation of bleeding, and to produce subsequent regulation of the cycle. Once hemostasis is achieved, the maximum daily dosage of "Premarin" must be continued to prevent recurrence of bleeding. This schedule forms part of cyclic estrogen-progesterone treatment for attempted salvage of ovarian function.

"Premarin" contains estrone sulfate plus the sulfates of equilin, equilenin, β-estradiol, and β-dihydroequilenin. Other α- and β-estrogenic "diols" are also present in varying amounts as water-soluble conjugates.

An "estrogen of choice for hemostasis is 'Premarin' in tablets of 1.25 mg. ... The usual dose for hemostasis is 2 tablets three times a day. If bleeding has not decreased definitely by the third day of treatment the dosage level may be increased by 50 per cent."*

*Fry, C. O.: J. Am. M. Women's A. 4:51 (Feb.) 1949

"PREMARIN"®

Estrogenic Substances (water-soluble)
also known as Conjugated Estrogens (equine)

Four potencies of "Premarin" permit flexibility of dosage: 2.5 mg., 1.25 mg., 0.625 mg., and 0.3 mg. tablets; also in liquid form, 0.625 mg. in each 4 cc. (1 teaspoonful).

from among
all antibiotics,
Neurologists and Neurosurgeons
often choose

AUREOMYCIN

because

It readily passes into the cerebrospinal fluid, the presence of meningitis making little difference in its concentration.

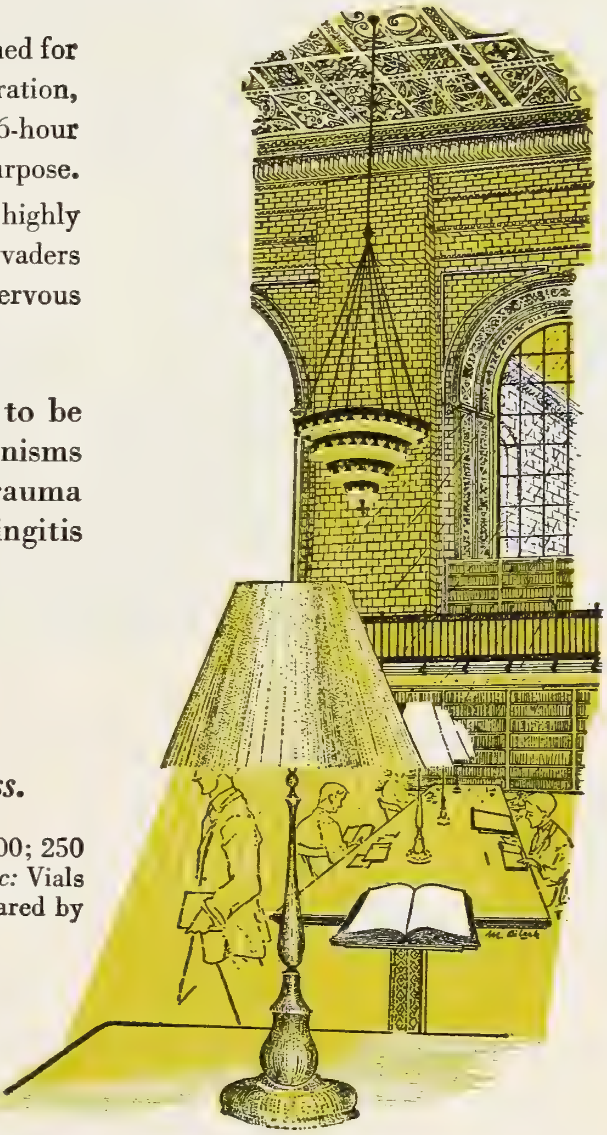
Measurable serum levels are maintained for as long as 12 hours after oral administration, oral doses of 5 to 10 mg. per kilo at 6-hour intervals being adequate for this purpose.

Aureomycin has been shown to be highly effective against those bacterial invaders commonly encountered in central nervous system infections.

Aureomycin has been reported to be effective against susceptible organisms in: Brain Abscess • Cranial Trauma Infection • Encephalitis • Meningitis

Throughout the world,
as in the United States,
aureomycin is recognized as a
broad spectrum antibiotic
of established effectiveness.

Capsules: 50 mg.—Bottles of 25 and 100; 250 mg.—Bottles of 16 and 100. *Ophthalmic:* Vials of 25 mg. with dropper; solution prepared by adding 5 cc. of distilled water.



LEDERLE LABORATORIES DIVISION

Cortone®

Safety in the Prolonged Control of RHEUMATOID ARTHRITIS

CORTONE
ACETATE

Successful clinical experience with Cortone in many *large series* of patients reveals the safety of this product. The administration of Cortone does not necessitate any measures that are not readily available to the physician in everyday practice. The use of simple laboratory tests (sedimentation rate, urinalysis, blood count, blood pressure, and recordings of weight), individualized adjustment of dosage, and careful clinical observation will permit most patients to benefit materially . . . without fear of undesired effects.

One investigator notes: "We have not been impressed by the severity or frequency of side-effects . . . The side-effects due to excessive adrenal cortical hormone disappeared when the hormonal agent was discontinued."

Norcross, B. M., *N. Y. State J. Med.* **51: 2356,** Oct. 15, 1951.

All Children Can Benefit from *this* Protective Hot Drink at Breakfast

In its widely distributed leaflet No. 268, "Eat a Good Breakfast," the U. S. Dept. of Agriculture states: "Summer or winter, there's something hot, as a rule, in a good breakfast.... Something hot is cheering and tones up the whole digestive route."

The problem of encouraging children to eat an adequately protective breakfast finds easier solution when Ovaltine in hot milk is recommended as a breakfast beverage. Many children clamor for a hot drink at the morning meal, and hot Ovaltine is the right kind of drink to recommend.

A cup of hot Ovaltine makes an excellent contribution of virtually all essential nutrients, adding substantially to the nutritional start for the day. It also serves in a gustatory capacity by enhancing the appeal of breakfast and making other foods more inviting.

The nutrient contribution made by a cup of Ovaltine is apparent from the table below. Note the wealth of essentials added to the nutritional intake by making the simple recommendation of adding a cup of hot Ovaltine to the child's breakfast.

THE WANDER COMPANY, 360 N. MICHIGAN AVE., CHICAGO 1, ILLINOIS

Psychoneurotics of Genius

Hawthorne, distinguished American novelist, is said to have been afflicted with a psychoneurosis from early childhood. His quiet life, wholly detached from the major activities of the times, was largely given over to brooding solitude.

The majority of psychoneurotics have no serious mental illness, but display merely an emotional imbalance which often can be greatly improved by appropriate psychotherapeutic and sedative management. In the treatment of psychoneurosis, particularly agitated, depressed and anxiety states, Mebaral is especially useful when tranquillity with minimal hypnotic action is desired. Sedative dose: Adults, from 32 mg. to 0.1 Gm. (½ to 1½ grains) three or four times daily. Children, from 16 to 32 mg. (¼ to ½ grain) three or four times daily. Supplied in tablets of 32 mg., 0.1 Gm. and 0.2 Gm.

The occasions of pleasure and pride which Dr. Harris finds in difficult surgical accomplishments occur more frequently these days than when he first began his practice. His skill has continued to develop. Furthermore, improved anesthesia has helped make possible the regular performance of certain kinds of surgery which at one time would have been extremely risky, if not impossible. Investigators in academic laboratories have joined their efforts with those of the pharmaceutical industry for . . . →

Oh Doctor—I can really walk again
Lilly

. . . the Development of Improved Anesthetics

"DOCTOR, your patient is ready." This classical statement as uttered by Morton in 1854, when he first demonstrated surgical anesthesia, is a phrase still commonly used by anesthetists. Since then, however, many developments have greatly improved anesthesia and aided the progress of surgery. Among these was the discovery of 'Metycaine Hydrochloride' (Piperocaine Hydrochloride, Lilly) in a university laboratory, where, in conjunction with Eli Lilly and Company, chemists were searching for a better local anesthetic. From a long series of chemically related substances which had been prepared, 'Metycaine Hydrochloride' was selected for extensive clinical evaluation. When used as recommended, it was shown to be no more toxic than procaine and to be capable of producing anesthesia more quickly, with greater certainty of effect, and for a longer period of time. These attributes of an improved local anesthetic are the reasons why 'Metycaine Hydrochloride' facilitates careful surgery.

SOME OBSERVATIONS ON THE RECOGNITION AND TREATMENT OF THE COMMONER FORMS OF HEPATIC CIRRHOSIS

C. J. WATSON, M.D.

Minneapolis, Minnesota

I FEEL gratified and deeply honored to have been invited to give the Henry Sewall Lecture for 1951. This has afforded a rewarding opportunity to gain some insight into the life work and character of a genuine scientist and teacher who played such an outstanding role in elevating the plane of medical education and research in Colorado. I am indebted to Dr. Waring for providing me with reminiscences and biographical information about Dr. Sewall. Not being well versed in the history of immunology, I was not previously aware that his discovery of antitoxin against snake venom antedated v. Behring's report of the preparation of diphtheria antitoxin. Recognition of this pioneer work was both inadequate and tardy, but in 1931 Dr. Sewall was awarded the Trudeau Medal of the National Tuberculosis Association, and in the same year the Kober Medal of the Association of American Physicians.

The recipients of this lectureship in previous years have set a high standard, and I feel genuine trepidation in seeking to follow them, and especially in attempting to do so through the medium of a topic as confusing as cirrhosis of the liver. There is little uniformity or general understanding as to the terminology and classification of the various forms of hepatic cirrhosis. This can be ascribed at least in part to two factors: (1) the loose and variable manner in which the term Laennec's cirrhosis is employed, and (2) the oft expressed concept that "there is but one cirrhosis." Many employ the term Laennec's cirrhosis interchangeably with portal cirrhosis, whether the liver be large or small, fatty or nonfatty and regardless of other characteristics. Laennec[37] really gave us little to go on except the bare statement that the liver is small and yellow. A more detailed description of what was undoubtedly the same disease had been given earlier by Matthew Baillie,[3] but unfortunately he used the poor and confusing name of "common tubercle." Despite the extensive studies of the cirrhosis problem by Mallory[41] and his emphasis on the fundamental distinction of certain forms, the idea of an essential unity of the cirrhoses gained many adherents. Only in the past decade has the pendulum been swinging in the opposite direction. One of the most important factors in this change was the study by many investigators of the transition of fatty liver to fatty cirrhosis,[10,11,12,21,47] both in man and animals. It has now become reasonably clear that the various forms of cirrhosis of the liver are perhaps the best divided into two main groups: those in which a fatty liver is an important primary feature of the disease, and those in which the cirrhotic liver is not fatty at any stage in its development. A suggested classification of cirrhosis along these two lines is given in Table I.

Several comments are needed with respect to the classification suggested in Table I. In certain instances it is not possible at the time of biopsy or necropsy to be certain that the cirrhosis was primarily fatty even though the history may strongly suggest this. The fat may have been

---

From the Department of Medicine, University of Minnesota Medical School and Hospitals. Aided by a contract from the Surgeon General's Office, U. S. Army, under sponsorship of the Commission on Liver Disease, Armed Forces Epidemiological Board.

The Henry Sewall Lecture presented on February 6, 1951, at the University of Colorado Medical School, Denver, Colorado.

UNIVERSITY OF MARYLAND LIBRARY Founded 1813 SCHOOL OF MEDICINE

TABLE I. SUGGESTED CLASSIFICATION OF HEPATIC CIRRHOSIS

- I. Primarily fatty in pathogenesis
  - A. Dietary deficiency ("Kwashiorkor")
  - B. Chronic alcoholism and dietary deficiency—*Laennec type*
  - C. Toxic fatty liver (arsenic, CCl_4, phosphorus, certain systemic infections)
  - D. Diabetic fatty liver
- II. Primarily non-fatty in pathogenesis
  - A. Viral or idiopathic
    - 1. Post-necrotic (toxic or coarsely nodular; healed acute atrophy)
    - 2. Diffuse portal (chronic hepatitis with fibrosis, mainly portal)
      - a. With hepatocellular impairment
      - b. Cholangiolitic (primary biliary; Hanot)
    - 3. Transitions and mixtures
  - B. Parasitic—Schistosomiasis
  - C. Syphilitic—probably only hepar lobatum
  - D. Brucellosis (?)
  - E. Obstructive biliary (cholostatic and cholangitic)
  - F. Metabolic error
    - 1. Hemochromatosis ("pigmentary" cirrhosis)
    - 2. Wilson's disease }
    - 3. Fanconi's syndrome } amino-aciduria
    - 4. Porphyria hepatica
  - G. Cardiac (central necrosis and fibrosis resulting from long standing chronic passive congestion)

largely removed by lipotropic substances, either a high protein diet or lipotropic substances such as choline, or methionine given over a considerable period prior to the histological study.

As noted in Table I, the relation of brucellosis to hepatic cirrhosis is questionable. There is much reason to believe it is at times causative.

The existence of a true cardiac cirrhosis is controversial.[40] In the autopsy material at the University of Minnesota, McCartney[45] was unable to find a single instance that met the criteria for a central, cardiac cirrhosis. A number of other investigators, however, have emphasized the occurrence of a central fibrosis in cases of longstanding passive congestion.[28,32,59]

I wish to consider certain of the more important clinical and laboratory features as well as the problems of treatment of the two forms of cirrhosis which are by far the most significant in the United States. The first and undoubtedly the most common is that for which, if it is to be used at all, the designation of Laennec's cirrhosis ought to be reserved. This is the primarily fatty cirrhosis most commonly encountered in the chronic alcoholic. The other type which I wish to consider is the primarily non-fatty cirrhosis which occurs as an idiopathic disease or as a sequel to infectious (viral) hepatitis.

At the present time at least, the distinction of these two most common forms is of considerable importance from the standpoint of prognosis and treatment. It may be emphasized that they are not observed in a constant ratio from one hospital to the next. In the large municipal hospitals in this country where the problem of alcoholism is encountered with the greatest frequency, the proportion of cases of so-called "alcoholic" (Laennec's) cirrhosis is much higher than in hospitals drawing material on a referral basis from a rural population.[25] In the material of this latter type which is characteristic of what we have at the University of Minnesota Hospital, cirrhosis in non-alcoholic individuals is relatively much more common, and in this group the incidence of previous jaundice and the history of infectious hepatitis has been significantly higher than in the control group.[25] The cirrhosis in these cases was consistently non-fatty, both early and late. In many instances the onset of the disease appeared to be of the nature of a sporadic hepatitis. This has been distinctly more common in women, and we have seen as many or more cases in young women as in those at or beyond the menopause. Ahrens and co-workers[35] have recently studied a group of cases in young women, characterized by arthralgia and hyperglobulinemia, in addition to other, ordinary characteristics of cirrhosis. In our own experience these features do not adequately delineate an independent form of the disease, as arthralgia is encountered with a fair degree of frequency in acute and chronic hepatitis as well as cirrhosis; and hyperglobulinemia of marked degree may be encountered in men and in older as well as younger women. We have been impressed, however, with the frequency of occurrence of non-fatty cirrhosis in young women. In a number of instances endocrine disturbances, either menstrual or secondary sexual, have been present for considerable periods prior to the first episode of apparent hepatitis. This, together with the sex incidence, suggests that endocrine disturbances may make the liver more vulnerable to attack. Matteini[44] has recently called attention to the high incidence of clinical and functional hepatic disturbances in women with menstrual irregularities and believes that the latter precede, rather than follow, the former.

In some of our cases the manifestations of cirrhosis have first appeared at varying intervals after an attack of epidemic hepatitis. Homologous serum jaundice was believed to be the starting point in a number of instances. In quite a few the onset was insidious without clear-cut evidence of an acute hepatitis. We have not seen any case of cirrhosis in which it appeared that infectious mononucleosis was causal, though recent reports have indicated this possibility.[39,49]

The question of relationship of viral hepatitis to diffuse cirrhosis is controversial, and it would lead me too far astray to consider the matter in any detail. It is my opinion, based on personal experience and various studies reported in the literature, that the relationship is reasonably well established, but it is quite clear that such a development is limited to a vary small fraction of the entire mass of cases of infectious hepatitis.

One gains the impression from much of the literature on cirrhosis[27] that the distinction between the so-called "post-necrotic" ("healed acute atrophy" or "toxic nodular") cirrhosis on the one hand and diffuse portal cirrhosis on the other is always sharp and distinct. While it is undoubtedly true that the extremes are usually distinguished accurately, it has been our experience that the border line between the forms included in the viral or idiopathic, non-fatty category of the above classification is often not clear-cut, and, as indicated, mixtures and transitions are observed. This is not surprising when one reflects that there are two important factors influencing the development of a more diffuse rather than a more irregular coarsely nodular type. These are (1) the occurrence in many, if not all, cases of infectious hepatitis, of small foci of necrosis, widely disseminated throughout the liver parenchyma, [2,42] and (2) the occurrence of chronic hepatitis, characterized by a persistent or recurrent inflammatory process throughout the liver with particular involvement of the portal spaces. [5,33,34,54,58,63] Our own experience indicates that while there are many clear-cut examples of coarsely nodular ("post-necrotic") as contrasted with a diffuse and more finely nodular cirrhosis, at the extremes of this large group, there are many and various instances between these extremes representing the interplay and persistence of these factors in varying degree. The earlier, excellent monograph of Bergstrand[6] clearly illustrates transitions between these infectious cirrhoses.

The more diffuse and the more prominent the portal fibrosis, the more likely that the term Laennec will be used in designation, even though it may be clear that the cirrhosis was primarily non-fatty, non-alcoholic and non-dietary in character. This is exemplified in a report by Bjorneboe and Raaschou[8] relating to the distinction of post-necrotic and "Laennec's cirrhosis." Here it is interesting to note that but 8 per cent of the latter were classified as alcoholics, that the cirrhosis was usually not fatty in type, and that difficulty was encountered in distinguishing post-necrotic from diffuse cirrhosis in some instances. One in particular was coarsely nodular in one area and finely nodular (diffuse portal fibrosis) in another. The great majority of cases included in this study followed upon an attack of hepatitis of unknown etiology.

There is a further important point indicating that some cases designated as "post-necrotic" represent more than a single attack of limited duration followed by a relatively static condition in which the necrotic areas are represented by large scars and regenerative nodules. This is the fact that the disease may be quite obviously *progressive* in character after a relatively mild initial attack, i.e., one without coma or the usual signs of acute or subacute atrophy.

The "cholangiolitic" type is one in which there is no evidence of necrosis, relatively little or no evidence of hepatocellular functional impairment for long periods, but only a chronic inflammatory process restricted to the portal areas and exhibiting the development of pericholangiolar fibrosis.[46,63] The clinical picture of this disease is identical with that described by Hanot.[22] The term "primary biliary cirrhosis" is often employed.[1] The designation "cholangiolitic" was first suggested by the pathologist Rössle,[56] and as indicated elsewhere[62,63] we have used the term more in a functional than in a histological sense, to represent the physiologic evidence of cholangiolar injury and regurgitation of elements of the bile into the blood. The term is also useful in indicating the probable restriction of the injury, at least during a certain stage in any given case, to the cholangiolar or intrahepatic bile canalicular system, with relative normality of the polygonal cells themselves. There is little doubt that cholangiolar injury is often just as severe or even more severe in many cases of hepatitis or cirrhosis in which liver cell function is also seriously impaired. Furthermore, there are many cases which, over a considerable period of time, exhibit only cholangiolitic phenomena, but after months or years gradually develop more and more hepatocellular functional impairment. This transition, in cases which for long periods have presented as a pure cholangiolitic cirrhosis, to one of more ordinary type with severe hepatic insufficiency, has been observed in a number of instances. Nevertheless, there are a significant number of cases of the cholangiolitic type in which liver cell function remains relatively undisturbed for long periods of time. It is particularly in this group that great difficulty is encountered in diagnosis, since laboratory aids in the distinction of extrahepatic from intrahepatic causes of jaundice depend mainly on tests of hepatocellular function. This difficulty will be considered again in the following. Ahrens and co-workers[1] have recently stated that none of their cases of primary biliary cirrhosis appeared to be related causally to infectious hepatitis. Yet one of the most remarkable of our own cases in this group gave a history of attacks of jaundice in the family and amongst the neighbors, thirty-three years earlier. At that time both the patient and her sister were in bed with fever and jaundice. The sister recovered completely, but the patient persisted in having intermittent or recurrent jaundice, at times with fever and abdominal pain, up to the period of her study here at age forty-eight. Because of fever, occasional chills and pain simulating gallstone colic, she had been operated on nine years earlier at which time a normal common duct was found. Liver biopsy then revealed a chronic hepatitis with mild portal fibrosis. Nine years later portal cirrhosis was well established, and the patient died of hematemesis from esophageal varices. This case has been reported in detail elsewhere.[63]

Certain important *clinical features* may now be considered with relation to the two principal forms: (1) the primarily fatty "alcoholic" or Laennec cirrhosis, and (2) the non-fatty viral or idiopathic cirrhosis.

In this country the history of outspoken alcoholism is usually evident in the Laennec or primarily fatty type. A history of viral hepatitis or of circumstances suggestive of it may be elicited in the primarily non-fatty group. It is important to seek carefully for an attack of jaundice coming on from two to four months after parenteral injection of any material that might conceivably contain or be contaminated with human blood serum; or, in fact, of needle puncture for blood tests of one type or another. In some instances the story of subacute diffuse necrosis of the liver with a very severe illness, and perhaps with a period of coma, is easy to elicit. After this attack the patient may have a relatively static hepatic insufficiency which permits some degree of activity but is easily demonstrable by physical and laboratory methods. In others the initial attack may be relatively mild without indication of any considerable degree of necrosis. The history of appearance of jaundice from two to four months after cholecystectomy or common duct surgery should lead one to inquire carefully as to the possibility of homologous serum hepatitis-cirrhosis. The natural assumption in such cases is that of a common duct stone or stricture, and if operation is carried out when the patient in reality is suffering from a diffuse hepatitis or cirrhosis, the result may be disastrous.[61]

Physical findings alone are often inadequate to separate the two common forms of hepatic cirrhosis which we are considering. Jaundice and ascites are encountered singly or in varying combination in either form. In general, it may be said that the emphasis is on ascites in the alcoholic or primarily fatty cirrhosis, and on jaundice in the viral or non-fatty cirrhosis.

It should be emphasized that advanced cirrhosis with hepatic insufficiency may be encountered *without* jaundice.[61] I have repeatedly seen cases of fatal hepatic coma due to cirrhosis, exhibiting fetor hepaticus and other evidence of failure of liver function, without visible jaundice. This combination has been most common following a sudden large hematemesis. The latter is undoubtedly responsible for further deterioration of liver function, but quite probably, also, a throttling of hemoglobin destruction so that bilirubin formation is at a minimum.

In the cholangiolitic or Hanot type, it is characteristic, of course, to have chronic jaundice, hepatomegaly and splenomegaly, without ascites. The pruritus which is so often observed in this type is quite rare in association with fatty cirrhosis. The majority of these cases eventually exhibit xanthelasma or xanthomata. The bulk of evidence indicates that in the so-called "xanthomatous biliary cirrhosis" the xanthomata are secondary, rather than a primary cause of the disease.

In our experience such manifestations as spider nevi, loss of hair, especially from the axillae, and fetor hepaticus are about equally frequent in the two groups. The occurrence and degree of the latter phenomenon in particular is of no little aid in assaying the severity of the hepatic insufficiency. Pigmentation or melanosis of the skin distinct from jaundice or hemosiderosis, is much more commonly encountered in the primarily non-fatty group. It is, of course, even more frequent in cases of hemochromatosis. Pigmentation not due to iron is at times associated with pruritus in cases of cirrhosis without jaundice and without elevation of the serum bile acids. The significance of this association is unknown.

Certain laboratory data deserve special comment. The leukocyte formula is of some significance in separating the two main forms. Thus, in the severe fatty cirrhosis of the chronic alcoholic it is not uncommon to observe a rather marked neutrophilic leukocytosis in association with even considerable fever, and, although this finding should induce a careful search for intercurrent infection, it is often not found, even at necropsy. In some of these cases a polymorphonuclear leukocytic exudate may be quite prominent in the cirrhotic liver,[14] but in others with the same degree of peripheral leukocytosis and fever we have failed to see this. Leukocytosis is much less frequently observed in the primarily non-fatty group. In fact in our own experience it has been associated only with intercurrent infection in these cases.

In cirrhosis the fractional serum bilirubin determination is of value under two circumstances: (1) When the prompt (1′) fraction is significantly increased ($>$0.25 mg. per 100 cc.), within a normal value for total bilirubin ($<$1.5 mg. per 100 cc.), in the non-jaundiced case. This, of course, is non-specific for cirrhosis and is often observed in other hepatobiliary disease. (2) When the bilirubin ratio [66]

$$\frac{\text{Prompt direct or } 1' \times 100}{\text{Total}}$$

is less than 30 in a patient with jaundice or with a total serum bilirubin above 2.0 mg. per 100 cc., and when the condition at hand is not a primary or uncomplicated hemolytic anemia. As a matter of fact, this combination is most often encountered in patients with cirrhosis and with a hemolytic component or outspoken hemolytic anemia.

From the laboratory standpoint, cirrhosis, of course, enters prominently into the problem of differential diagnosis of jaundice. The laboratory procedures of aid in this respect depend in the main on alterations of hepatocellular function. In extrahepatic obstructive jaundice such alterations commonly are slight or absent, while in the usual case of parenchymal or hepatic jaundice, including cirrhosis, the alterations are sufficiently marked to indicate with a fair degree of certainty that the jaundice is due to a diffuse disease of the liver, rather than a mechanical obstruction in the biliary tract. The distinction is perhaps of chief importance with respect to the question of whether an operation is indicated. There is perhaps no area in medicine in which it is more desirable to avoid a mistake in this regard. General anesthesia and a formal operation on a patient with a primary diffuse disease of the liver may be followed shortly by profound hepatic insufficiency, coma, and death. On the other hand, an equally great injustice may be done by failure to operate on a patient with a common duct stone or even a carcinoma of the biliary tract. In the ordinary case of cirrhosis a careful history and physical examination with attention to some of the above details, considered together with a reasonable number of well-chosen laboratory procedures, will very often provide the right diagnosis. Mistakes are most likely to be made in that group of cases in which hepatocellular function is relatively less and cholangiolar function relatively more impaired, as in the "pure" type of cholangiolitic cirrhosis. Here the tests which we ordinarily rely upon to indicate a diffuse hepatocellular functional impairment may be entirely normal or only slightly disturbed. The cephalin cholesterol flocculation test is often negative. The thymol turbidity test may be increased even considerably, but since in these cases there is frequently a hypercholesterolemia, and since the thymol tubidity test is much more positive under these circumstances, it becomes less useful in differential diagnosis. The alkaline phosphatase is commonly elevated to a marked degree along with the hypercholesterolemia, and the serum bile acid level is usually elevated. There may be relatively little urobilinogen in the urine. Thus, one is left with the problem of relatively painless jaundice, an enlarged liver, and sometimes a palpable spleen and a liver function profile quite compatible with an extrahepatic biliary obstruction. In some cases there may be mild evidence of hepatocellular functional impairment but not sufficiently outspoken to enable one to make the distinction on this basis alone. Another confusing feature in this particular variety of cirrhosis is the occurence of the pseudo-gallstone colic with or without fever and chills.[61,63] This may simulate cholelithiasis so exactly that a distinction is impossible.

Our policy for some time has been to subject doubtful cases to a small laparotomy under local anesthesia in the region of the gall bladder. Neither opiates nor barbiturates should be given. The gross appearance of the liver is noted and a liver biopsy is taken under direct vision. If the cystic duct is patent, cholangiography is then carried out through the gall bladder, while the patient is on the table. If the common duct is visualized and not dilated, and if the contrast medium flows readily into the duodenum, nothing more is done If the common duct is dilated and there appears to be obstruction at the ampulla, the incision may be extended and a more formal exploration of the duct may be carried out under general anesthesia. We are increasingly convinced that this method has a great deal of merit in avoiding jeopardy to the patient whose jaundice is due to hepatitis or cirrhosis.* Figure 1 shows a cholangiogram obtained in this way in a case of cholangiolitic cirrhosis. The common duct is not dilated, and the contrast medium flows readily into the duodenum. Prior to this study and a liver biopsy carried out at the same time, there was a serious question in this case as to the possibility of an extra hepatic obstruction.

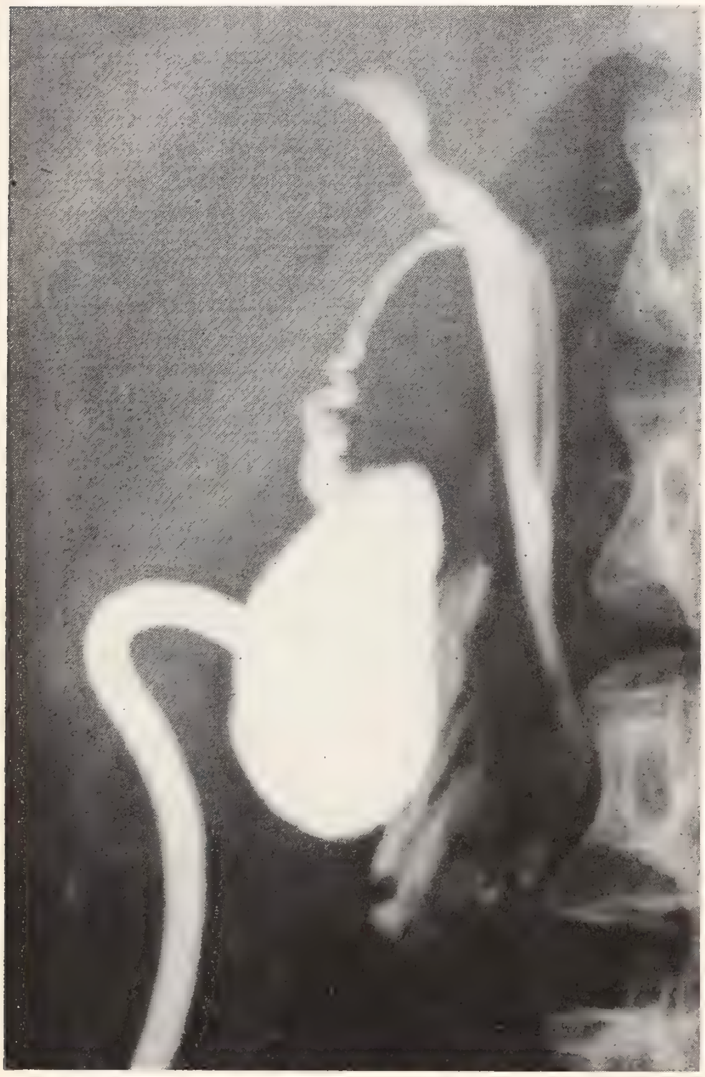

Fig. 1. Case E. N., a woman, aged forty-eight. Cholangiolitic cirrhosis. Cholangiogram through gall bladder under local anesthesia. No evidence of bile duct obstruction or abnormality.

Considerations of Treatment

We must readily admit that we lack any very specific therapy for hepatic cirrhosis. Nevertheless, it has become increasingly apparent in recent years that, of the two main forms of the disease which we have been considering, the results of certain general measures are often remarkably good in the primarily fatty group, while in the viral or non-fatty group there has been but little evidence that any of the measures thus far employed have been beneficial. The important contribution and subsequent experience of Patek and his co-workers[51,60] with a diet plentiful in protein and vitamins undoubtedly has led to a much more favorable attitude generally as to the prognosis of patients with cirrhosis. It appears however, that the good results which they are now able to report after a period of more than ten years[52] are limited to alcoholic fatty cirrhosis and that their statistical evidence of improvement and indeed of survival in these would be still better if the relatively small number of cases of post-hepatitis cirrhosis were omitted from their calculations. Patek[50] has evidently made no attempt to divide his material along the lines of the present classification, and he uses the term Laennec's cirrhosis in a much broader sense, and, it is believed, for a much more heterogeneous group.

In cases of Laennec's cirrhosis, using the term only as presently defined, it is quite clear that bed rest, abstinence and a good diet are often followed by dramatic improvement. Patients who are able to eat and whose livers *are still enlarged* have by far the best prognosis.[8,61] Those with small livers or with persistent and marked anorexia may fail to show any significant improvement, even with parenteral nutrition and various supplements. Nevertheless, we have found it difficult to determine any definite borderline, clinically, beyond which a patient is unable to recover, at least to a point compatible with comfort and a reasonable existence. In some of our cases liver biopsy at the outset has shown the most striking degree of fatty cirrhosis and disorganization[61,64] in spite of which after a variable period of time and following many and various therapeutic measures, recovery to a relatively normal state has been observed. In some instances even, in which jaundice ascites and somnolence were prominent at the outset, this recovery has been so complete that the physical examination and many of the liver function tests have returned entirely to normal, and only with a battery of tests has it been possible to detect some residual impairment of liver function.[61] Such individuals undoubtedly could pass a life insurance examination except for the history of their illness. Unfortunately, a reversion to their alcoholism all too often results in renewed progress of the cirrhosis. There are, of course cases of severe "alcoholic" fatty or Laennec's cirrhosis that fail to respond to therapy and succumb, either to hepatic insufficiency, blood loss, or intercurrent disease, or a combination. As mentioned earlier, the fat may be removed from the liver, at times quite completely, due to the lipotropic substances, but this is not necessarily followed by improvement even though the liver becomes considerably smaller. It is not unlikely that the determining factor in the prognosis is the *mass of relatively normal liver cells still present,* both to resume an improved function and for normal (not adenomatous) regenerative activity.

---

*Study in progress with Dr. Richard Varco, professor of surgery, University of Minnesota. Peritoneoscopic cholangiography, as recommended by Royer and others,[29,57] has been demonstrated to be equally useful for this purpose.

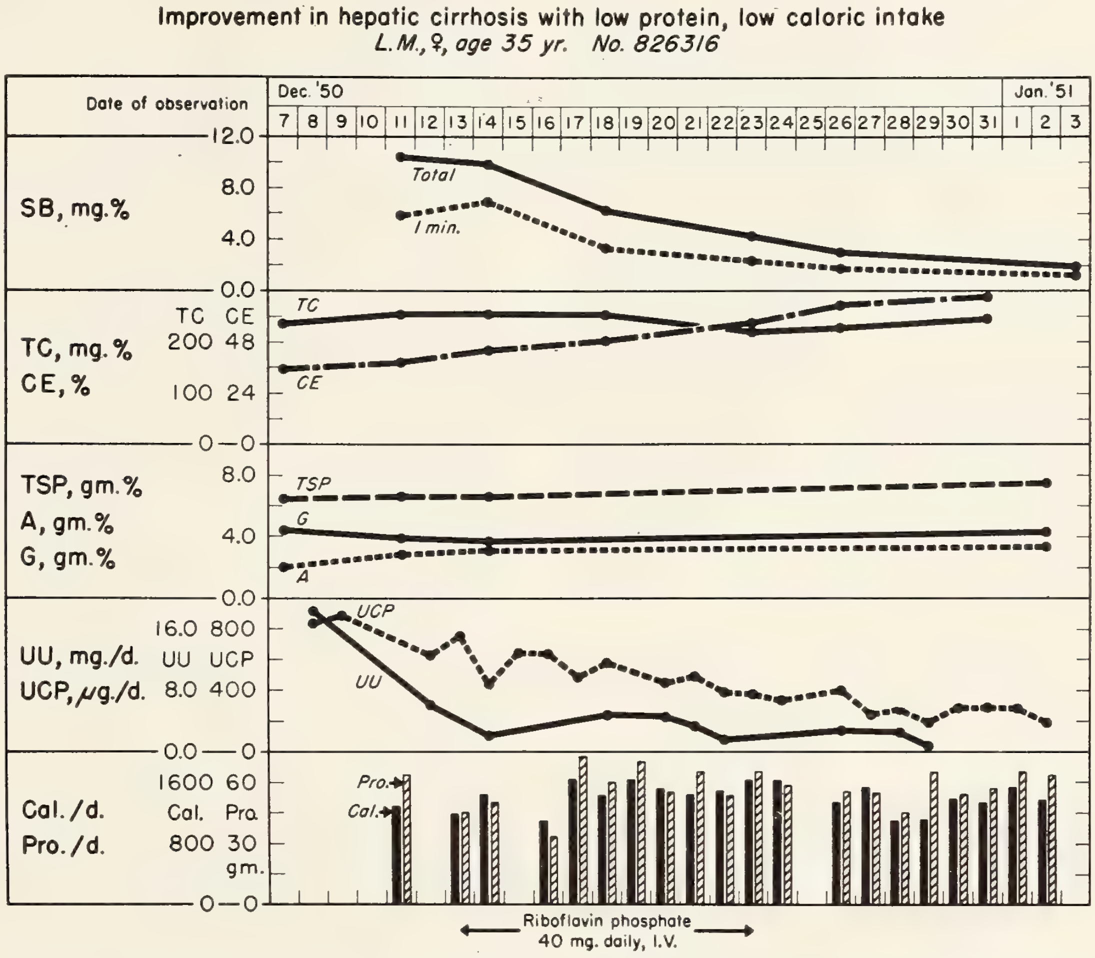

Fig. 2. Case L. M., a woman, aged thirty-five. Chronic alcoholism with cirrhosis, jaundice and ascites. Improvement with low protein, low caloric intake. Riboflavin phosphate was given in relation to a study of porphrin metabolism, but it is probable that improvement had commenced before it was started.

It has not been possible to determine what measures are of greatest significance in promoting recovery. The production of fatty cirrhosis in animals as a result of choline deficiency and its occurrence in human dietary deficiency without alcohol; also the improvement reported by Patek and others, following a liberal intake of protein and vitamins argue in favor of dietary factors as being of principal significance. Nevertheless, it is now clear that with rest and abstinence, striking improvement will often occur on diets relatively low in protein[30] Eckhart and co-workers[15] observed improvement in cases of "alcoholic" cirrhosis receiving a diet of carbohydrate almost devoid of protein but containing small amounts of choline and Vitamin B complex. In Figure 2 data are shown from a case of "alcoholic" fatty cirrhosis in which marked improvement occurred on a relatively low calorie and protein intake. Recent studies indicate, however, that no improvement occurs if calories are supplied as glucose alone, without choline or protein.[53] This is in accord with the observation of Best and co-workers[7] that fatty liver is promoted in the rat by feeding glucose, or alcohol, without choline. Nevertheless, these observations do not exclude the possibility that alcohol *increases* the requirement of choline, perhaps by interfering with its function in the liver. This, in fact, has been suggested by certain recent experiments of Klatskin.[31] If this were true, it would readily explain the occurrence of outspoken fatty cirrhosis in some individuals who have been drinking excessively for years but give histories of an adequate protein intake and are fully supported in this story by members of their families. A critical experiment that is much needed, but for obvious reasons difficult to carry out, is that of continuing cases of "alcoholic" fatty cirrhosis on alcohol, under controlled conditions in the hospital. A similar study has been carried out with respect to alcoholic polyneuritis, and this yielded the interesting information that the controlled cases not receiving alcohol responded more quickly to dietary and vitamin therapy.[9]

It appears inescapable that striking individual differences exist as to the ease of development of cirrhosis in chronic alcoholics, some with long histories of severe alcoholism and poor diet nevertheless failing to show the least evidence of cirrhosis; others, as already mentioned, with outspoken fatty cirrhosis but without any history of dietary deficiency. It cannot be denied that there may be important constitutional variance in the tendency to cirrhosis, and that this might be ascribed to the relative efficiency of utilization of lipotropic factors, especially choline. There are certainly differences between species in respect to the effect of alcohol on porphyrin metabolism, the disturbance of which in cases of human cirrhosis is probably a reflection of a disturbed cellular metabolism in the liver. An increased excretion of type III coproporphyrin characterizes acute alcoholisim in humans and is found in human alcoholics with cirrhosis, for variable periods after cessation of alcohol.[60,65] In rats[24] and dogs,[20] however, these increases have not been observed, either in relation to acute alcoholism or dietary fatty cirrhosis, either with or without alcohol.

It is doubtful that the addition of choline or methionine provides any benefit for the patient with "alcoholic" cirrhosis, beyond that to be expected from a normal intake of protein. Preliminary studies with large amounts of vitamin B_{12}, which has also been shown to be lipotropic and choline sparing, lead to the same conclusion.

A good deal has been written about the value of crude liver extract in the treatment of cirrhosis of the liver. Ralli and co-workers[55] have recently reported a difference in survival rates in patients receiving crude liver extract ("intraheptol") intravenously, as compared with those not so treated. In this report, however, it was not stated whether the controls returned at as regular and frequent intervals to receive a placebo instead of liver extract, and, since the entire group consisted in the main of alcoholics, this would seem to be an important requirement. We have not been able to convince ourselves of the beneficial effect of crude liver extract. We have often seen patients who were receiving it improve, but only after a long period of time during which other measures were employed, so that the improvement could scarcely be ascribed to the extract. Actually, a controlled study of the effect of any given substance in the treatment of hepatic cirrhosis is attended by unusually great difficulty. Such a study requires hospitalization and a base line period of observation, and, as already noted marked improvement may occur during the control period. On the other hand if the patient is very ill, one does not feel justified in attempting a controlled experiment with one substance since a number of days would be required, during which he would be denied the possible benefit of other measures.

It was generally hoped that salt-poor human albumin (prepared by Cohn's method) might be of great value in the treatment of hepatic cirrhosis. Its value, however, appears to be limited largely to certain patients with ascites, if given shortly after the abdomen has been tapped relatively dry[18,36] and particularly if used in conjunction with mercurial diuretics and a very low sodium intake.[17,23] Some caution is required in the administration of albumin, as pulmonary edema and fever have repeatedly been observed after large amounts.[64] It appears, too, that the likelihood of hematemesis from esophageal varices is distinctly increased by administration of albumin in an amount sufficient to have any effect on acites.[18,23]

The appreciation of the great significance of sodium for the accumulation of ascitic fluid is one of the more important recent advances in the treatment of cirrhosis.[16,17,38] Various studies have shown that if a low salt diet is to be effective, it must contain less than 1 gram of sodium chloride (0.4 gm. sodium) in twenty-four hours and preferably not more than half of this amount. [16,17] The use of an ion exchange resin to permit a more liberal intake of sodium, without absorption from the intestine, has proven of some value but has distinct danger.[19]

I have striven thus far to focus your interest principally upon the two forms of hepatic cirrhosis most common in this country. It may be well in closing to give brief attention to another member of the primarily non-fatty group, namely, hemochromatosis. This is the most important representative of the metabolic subdivision given in Table I. It is invariably a hypertrophic cirrhosis, in the broad sense, and the size of the liver may attain unusual proportions. It should be emphasized that while the disease is commonly termed "bronze diabetes" the evidence of cirrhosis and the pigmentation of the skin may appear well in advance of the glycosuria and in some instances enlargement of the liver due to iron deposition may be present without diabetes and with very little pigmentation of the skin. Liver biopsy is of the utmost value in the diagnosis of such cases, indeed of the disease quite generally. The skin biopsy may be negative for iron, even in the presence of considerable degrees of pigmentation.

An intriguing method of treatment of this form of cirrhosis has recently been suggested.[4,13] This depends upon the concept that the primary disturbance in hemochromatosis is one of abnormal iron absorption and storage and that the cirrhosis is secondary to the extensive deposits of iron. The method consists of repeated bleeding, over long periods of time, to force utilization of the iron stored in the liver and perhaps in this way to bring about improvement of the cirrhosis. Davis[13] has reported cases in which it appears that this may have been achieved to some extent. Howard and associates in this clinic have been following the case of a surgeon with hemochromatosis who has been unusually co-operative in permitting repeated blood letting over a three-year period.[26] In this span of time approximately 100 liters of blood have been removed. The liver is still enlarged, but it appears to be distinctly smaller than at the outset. The only evidence of improvement of liver function has been a slight increase in the serum albumin, and an increase of the cholesterol ester percentage. The pigmentation of the skin has clearly diminished. With this there has been an improvement in the patient's general status, his feeling of well-being and his ability to work. Only time will tell whether the disease can be held in abeyance permanently or whether even an outspoken remission can be brought about in this way. Of course, as time goes on a major difficulty is that the veins become increasingly less available to phlebotomy. In this connection one is reminded that a deliberate hookworm infestation has been employed by French clinicians in the treatment of some cases of polycythemia vera. Actually, this method would appear to be even more logical for hemochromatosis, though just as repugnant.

Summary and Conclusions

1. Hepatic cirrhosis is not regarded as a single disease with variations but rather as a group of diseases of widely varying etiology in which chemical, dietary, infectious, and metabolic factors are all of importance, either individually or in combination.

2. It is useful and logical and in accordance with present available knowledge to divide the cirrhosis into two main groups, those that are primarily fatty in pathogenesis and those that are primarily non-fatty. The principal representative of the former group in this country is the fatty (Laennec) cirrhosis of the chronic alcoholic, while the non-fatty group is represented mainly by the cirrhoses, either post-necrotic, diffuse portal, or transitions, following upon an attack of infectious hepatitis or occurring without known etiology. Cases which are indistinguishable from those following hepatitis, but which may have a differing etiology either develop insidiously or follow immediately upon an attack which may represent a sporadic infectious hepatitis. This form is more often observed in women. A special variety or stage in the large group of primarily non-fatty cirrhosis is the relatively pure cholangiolitic or primary biliary cirrhosis which undoubtedly corresponds with what Hanot originally described. This variety is of particular importance because of the ease with which it is confused clinically with extrahepatic biliary obstruction. In

this respect the value of cholangiography under local anesthesia is discussed.

3. The results of treatment of cirrhosis are much better than was formerly believed, but it is emphasized that the good results are limited largely to the primarily fatty group (in this country mainly in chronic alcoholics). The relative importance of various factors responsible for these good results is not yet clear, but it appears that the value of rest and complete abstinence may have been underestimated. The possibility is considered that alcohol may increase the choline requirement.

4. The treatment of ascites is centered upon the importance of a low sodium intake and of promoting sodium excretion, once due attention has been given to the simple factors just referred to.

MORE AUTOPSIES NEEDED

"An increase in the proportion of autopsies . . . would lead to more accurate diagnosis" in infants' deaths, says Mr. J. W. Brower, acting director of the Division of Vital Statistics, Minnesota Department of Health. A report recently issued by that division states that autopsies are not common in the smaller cities and rural areas of the state. For the first part of 1951, Duluth reported the largest proportion of autopsies, followed by Minneapolis and Saint Paul.

The Divisions of Vital Statistics and Maternal and Child Health are making a statistical analysis of infant deaths from birth and death records of Minnesota infants. This study indicates that 806 infant deaths occurred in the state during the first five months of 1951, and that 53.6 per cent of the infants who died weighed less than 5 pounds 9 ounces at birth. These infants were premature according to the widely accepted definition of the term. Fewer than 11 per cent of the deaths due to premature birth were autopsied. Congenital malformation was the second highest cause of death among the 806 infants, accounting for 171 deaths.—*Minnesota Health,* January, 1952.

REHABILITATION OF THE HEMIPLEGIC PATIENT

JOE R. BROWN, M.D.

Rochester, Minnesota

DURING the past few years increasing attention has been paid to the retraining of patients who have hemiplegia. With the increasing aging of our population this problem promises to be of even greater importance in the future than in the past. The fact that satisfactory results can be obtained is indicated by the experience of Leemhuis and Brown, who have reported that at least 85 per cent of 105 hospitalized hemiplegic patients treated showed significant improvement under an integrated program of therapy. Such a program can be adapted for the treatment of patients in the home or as outpatients. In the management of a patient who has had a stroke it is necessary to take many factors into consideration. The more one can learn about his total situation, the more readily can one deal with specific problems as they arise.

It is possible to describe the management program according to the stage of the illness of the patient. The care of the patient during the acute illness is beyond the scope of this paper. Ordinarily one can consider this stage to be terminated when the major immediate threat to life seems to have subsided. In general, the acute stage lasts from two to ten days and merges into the subacute stage. At this point it is important to evaluate the extent of the disability. There may be severe weakness in the arm, the leg or both. There may be associated hemianesthesia and hemianopsia. The patient and his family should be gently but confidently introdduced to the idea that measures are being started for the purpose of aiding him to walk again.

Early in the subacute stage the paretic extremity is frequently flaccid but later it becomes spastic. Because of immobility and spasticity, contractures are prone to occur and may make their appearance within ten days. Common sites of early contractures are the shoulder, hip and knees. Spastic contractures of distal joints may develop later. Prevention of contractures depends on the early institution of passive motion daily through the full joint range. Proper positioning in bed will help avoid flexion at the hip and knee, as well as inversion of the foot. The correct position can be maintained by the use of sandbags, footboards, and so forth. If trained therapists are not available, nurses or responsible relatives can be instructed in the proper use of passive motion.

The duration of the subacute stage will generally vary from three to six weeks, depending on the cause, severity and location of the brain lesion. In general, a cerebral hemorrhage requires a longer period of rest in bed than does a cerebral infarct. The presence of a complicating medical condition may also prolong this period. During the subacute stage the patient is encouraged to move and use the affected extremities. At the same time he is stimulated to assist with his daily self-care needs[1] (Table I). By the end of the subacute stage he should be capable of the first eight self-care activities listed.

The early convalescent stage begins when the patient is permitted out of bed. At this time he is instructed progressively in the next seven self-care activities and the beginning ambulation activities (Table II). At this point the patient should be protected against possible falls. Care should be taken to attain full extension of the knee of the paretic leg. A solid table, posts of a bed, and so forth, may be used to substitute for parallel bars. The exercises at this time should be taken over by the patient as much as possible. Passive motion can be obtained by the use of pulley assistance. Muscle power in paretic muscles can be increased by utilizing the principle of progressive resistance exercises.[5] At the start the patient should be expected to lift ten times successively an amount which is one half of his maximal capacity for a single lift through the range of that particular joint. If he is unable to move the extremity through full range against gravity, the final few degrees he lacks may be completed by a therapist or by a properly instructed relative (active assistive exercises). Re-education exercises for the development of finer skills will probably require the supervision of a trained therapist. For details of the use of specific exercises, a standard text on the subject is suggested.[12]

From the Department of Neurology and Psychiatry, Mayo Clinic, Rochester, Minnesota.

Read at the fourth annual Clinical Session of the American Medical Association, Cleveland, Ohio, December 5 to 8, 1950.

TABLE I.—SELF-CARE*

Activity	
1. Change position in bed	Below 16% 0
2. Feed self	
3. Wash hands and face	
4. Brush teeth and comb hair	16%-32% +1
5. Write name and address	
6. Use telephone	
7. Sit up for six hours	
8. Get from lying to sitting position	
9. From sit on bed to stand	33%-60% +2
10. Tie pajama bottoms	
11. Put on and take off shoes	
12. From bed to wheelchair to bed	
13. Sit and arise from armless chair	
14. Put on and take off pajama bottoms	
15. Put on and take off pajama tops	
16. In and out of chair at table	61%-84% +3
17. Shave self	
18. Pick object off floor	
19. Use toilet without assistance	
20. In and out of car	
21. Tie shoes	
22. Put on and take off braces	85%-100% +4
23. Clothe self completely	
24. Take bath without assistance	
25. Get from floor to stand

TABLE II.—AMBULATION*

Activity					
1 Arise and stand with aid in parallel bars					Below 16% 0
2. Arise and stand without aid in parallel bars					
3. Shift weight from foot to foot in parallel bars					
4. Walk in parallel bars with assistance					16%-32% +1
5 Walk in parallel bars without assistance					
6. Walk with assistance of instructor					
7. Walk without assistance, instructor by side					
8. Arise to stand from wheelchair without aid					
9. Walk alone, using crutch					33%-60% +2
10. Climb stairs with railing					
11. Climb stairs with rail backwards					
12. Walk sidewards and backwards					
13. Walk alone using cane					
14. Walk on ground and carpeting (rugs)					
15. Open and close door from stand					
16. Climb bus steps					61%-84% +3
17. Climb curb					
18. Climb steps without hand rail					
19. Discard wheelchair					
20. Distances (feet)........	25	50	75	100	
21. 48 feet—seconds........	85	80	75	70	
22. Distances (feet)........	150	200	300	400	85%-100% +4
23. 48 feet—seconds........	65	60	50	45	
24. Distances (feet)........	500	600	700	800	
25. 48 feet—seconds........	40	35	30	25	

*From Leemhuis and Brown by permission of the Journal-Lancet.

During the later convalescent stage the remainder of the self-care and ambulation activities are added to the patient's program. He is expected to take the initiative for continuing to utilize each new accomplishment in his daily activities.[4] The patient at this point is encouraged to take an increasing part in family affairs and household tasks. The development of hobbies, social events and group contact are all a part of his retraining program. The convalescent stage may be expected to last in the neighborhood of three months.

The stage of social and vocational readjustment follows the convalescent period. At the present time, many of the older patients with hemiplegia, particularly those with complicating medical disorders, must be satisfied with a goal of self-care, moderate ambulation and avocational pursuits at home. Others, especially in the younger age group, can achieve economic independence. Because of the disability it may be necessary for the person to learn a new vocation. The resources of such agencies and facilities as the state vocational rehabilitation units and local social workers can be utilized.

So far we have been discussing the relatively uncomplicated physical portion of a program of rehabilitation. Such measures are subject to considerable standardization. In the course of retraining patients with hemiplegia, complications of various sorts may well develop and require considerable individualization of the program of therapy.

Perhaps the most common medical complication is the presence of heart disease. This is followed in frequency by urinary difficulties and orthopedic disabilities. The development of thalamic pain or an aphasia from involvement of the major cerebral hemisphere will present perplexing treatment problems. Any detailed discussion of the management of these problems is beyond the scope of this paper.

The emotional readjustment of the patient is an ever-present problem in the management of these patients. The occurrence of a stroke with all of its actual and implied significance—physical, intellectual, emotional, financial and social—is actually a catastrophic blow to the patient and to his family. The patient is faced with physical disability which may well seem overwhelming. He has available to meet this a damaged nervous system with reduced capacity for adjustment.

In the presence of brain damage psychologic and intellectual capacities may be reduced to varying degrees, a process which Hughlings Jackson named dissolution. Affected in this process are the abilities to abstract, to integrate, to modulate emotions, and to select adaptive responses.[8] The damaged nervous system is left shallower, the top is lower, there is less of the person. The effects of this process will appear even though the patient's memory and conversation show no apparent deficit. With reduced ability to abstract, the patient misses fine transitional distinctions, is slow to grasp the essential features of a given experience and has difficulty in keeping in mind simultaneously two or more factors. Because he does not understand fully the implications of a situation, his ability to integrate information and form judgments is poor. He has a predetermined bias which interferes with his ability to relearn and interpret. There may be limited ability to modulate emotional responses, leading to unwarranted outbursts of irritability, crying or laughing. Behavior tends to become stereotyped, compulsive and concrete because of the loss of the most highly flexible, complex and voluntary mechanisms. The patient with brain damage has lost some of his capacity for free voluntary selection of behavior and must act in a more automatic manner.[2] Simple tests for the estimation of the amount of brain damage are available.[14]

Psychotherapy in the management of patients who have hemiplegia is an essential part of the treatment regimen. The physical disability imposes limitations on the patient's personal, vocational and social activities and threatens his position within his family or group. The psychologic effect of brain damage may significantly repair his capacity for adaptation. These two factors interact with the basic personality structure of the individual. This constellation of forces may well have an effect which is catastrophic. Suggestion, reassurance and support by the physician can be potent forces in preventing or ameliorating a catastrophic effect. Many patients will respond with hope to a well-planned, active therapeutic program which says in effect, "You will be able to walk." Appropriate measures must be taken to bring the family into the therapeutic regimen, to help educate them in their role and to deal with situational problems within the family group.

In directing an integrated treatment program, it is possible to approach directly by symptomatic management various problems as they arise.[3]

Confusion is a constant finding during the acute stage of a stroke. The duration of the confusion will depend largely on the extent and location of the brain lesion. It is important to protect the patient against self-harm during this stage. Particular attention must be paid to fluid and electrolyte balance, as well as caloric and vitamin intake. As soon as possible a simple daily schedule should be started. Regularly scheduled attention to the bowels and bladder will reduce soiling. Gradual habit training in the simple self-care activities of personal hygiene, turning in bed, feeding, and so forth, is gradually added. Social contacts are kept at a very simple level.

Apprehension and fear are generally disguised or kept suppressed by various defenses. They may appear during the acute stages as delirium, which is actually fear mixed with confusion. The patient's fears under such circumstances become *his* reality. He must be protected against self-harm and should be encouraged to accept reassurance and support from someone he trusts. Properly chosen sedative and narcotic drugs are of distinct value. They should be quick-acting drugs that are rapidly metabolized. Slow-acting, slowly excreted drugs often produce a prolonged twilight state of consciousness that makes unmanageable an otherwise mild delirium.

Anxiety and tension reactions are particularly common in the early stages of retraining. They tend to reappear when new experiences are anticipated, for example, when the patient first is permitted to stand or walk, when he goes outdoors for the first time, or when a return to work is planned. The capacity to adapt is limited by the physical disability, by the psychologic effects of brain damage, and by long-standing personality characteristics. On approaching a new problem the hemiplegic patient tends to feel insecure, anxious and fearful, and because of the total catastrophic effect of the "stroke" he is less able to tolerate anxiety. To defend himself against this anxiety he may be forced to resort to compulsiveness, irritability, depression, or indifference and apathy. When possible, such reactions should be foreseen and avoided. Encouragement, reassurance and support will help considerably in allaying the feelings of anxiety. The activity program should be of progressive difficulty but should be undertaken in easy steps. It is particularly important to avoid tasks which are overwhelming to the patient.

Compulsiveness, stereotyped behavior, perseveration and rigidity result directly as concomitants of brain damage, and they may also occur as an adaptation to any stress situation. The marked limitation of flexibility will delay a retraining process and requires an attitude of increased patience on the part of the physician and family. Retraining should begin early because it is difficult to change unfavorable habits which have become rigidly fixed. Sudden changes or complicated situations are likely to produce confusion and return the patient to increased rigidity of response. It is important to utilize the compulsiveness of the patient by developing a schedule of daily activities, utilizing the patient's natural needs and rhythm. A simple schedule would include daily self-care activities of toilet, dressing and eating. Ambulation, recreation, handcraft and social activities are gradually added to the daily routine. Family responsibilities and vocational readjustment are later steps which can be gradually assumed by some patients.

Irritability, impatience and stubbornness are characteristic of many patients with brain damage, particularly patients whose pre-illness personality showed evidences of this mood. Fortunately the outbursts of irritability are generally short-lived and there are times when the patient is more amenable. It is generally wiser to be permissive when the patient is obstinate and then induce him to accept a suggestion when he is more tractable. On rare occasions it may be wise to establish by an interested, calm, firm approach that the physician is boss, but it is ordinarily wise to avoid such a showdown. Frequently the irritability will be most marked in relation to other members of the family. Consequently an inquiry into the attitudes and behavior of the family group is indicated. As soon as practicable the patient is permitted to take on responsibility for his daily activities to reduce the frustrations of inactivity. Competition with other patients, hobbies, diversions and social contacts all combat irritability by fostering the independence of the patient.

Depression is a common response to serious illness and may be particularly persistent in patients with generalized brain damage. It appears to be most common in individuals whose pre-illness personality has shown moderate aggressiveness coupled with moderate needs for dependency and support. Such a person feels guilty and self-accusatory about giving in to his dependency needs. In setting up a treatment program it is important to avoid assigning a task at which the patient will fail, since any failure tends to produce self-accusation and increase the depression. To prevent rut formation, the program should be started early with simple activities. A period of lightened depression commonly occurs in the late afternoon, a time which can be used to begin activities. Early, the activities should be simple and should require little effort. Recreation, physical activities and social contacts are gradually added within the patient's tolerance. The load should be progressive but should never exceed his capacity at the time. Responsibilities must be avoided until the patient is well recovered. A depressed patient may feel the obligation to take on responsibilities before he is actually prepared to cope with them.

Somatic complaints, fatigability, hypochondriacal attitudes and conversion symptoms may be unconsciously utilized to avoid the tension and anxiety of facing new situations. Such attitudes occur particularly in individuals who have a lifelong history of passive dependent relationships with other people. Such patients unconsciously utilize a serious or disabling illness to maintain the dependent relationship by conversion symptoms, fatigability and somatic complaints. In the treatment of a patient with such findings it is important to recognize that the symptoms are serving a useful purpose in fulfilling his dependency needs. Any sudden opportunity to get well is also a threat to the need for dependence and is likely to exacerbate the symptoms. An inquiry into life situations, previous personality and family attitudes is important. It is often helpful to foster in the patient a reaction of dependence on the physician and the therapeutic measures. It is important to see that early the patient gets adequate "tender loving care" to avoid forcing him to wheedle attention by somatic complaints. As the treatment schedule is established the physician is able to withdraw his support gradually and encourage the transfer of the dependence to the routine of daily activities. Prolonged symptomatic therapy in which the patient does not actively participate should be avoided.

Indifference, apathy and withdrawal may be the more or less direct result of brain damage but are usually conditioned by the basic personality make-up of the individual. They represent the ultimate in defense against feelings of anxiety, resentment, pain and depression. Goldstein spoke of this as a catastrophic reaction to a situation which overwhelms the adaptive capacities of the person. A patient who has developed or has the capacity for developing a catastrophic reaction must be handled with great care. Approaches must be gentle, reassuring and tentative. Attempts must be made to learn of factors which arouse in the patient a spark of interest. The therapist must woo the confidence of the patient. Very slowly the retraining procedures may be begun. Extreme caution must be observed to avoid new frustrations which might again threaten the defenses of the patient.

The concept of body image plays an important role in the readjustment of a hemiplegic patient. There are numerous hypotheses and observations related to the neurologic, psychologic and psychiatric aspects of the body image (Kolb). For the purposes of the present discussion a few observations may suffice. A concept of the body image is essential in the daily activities of every human being. The infant begins to develop the concept with his early exploratory movements of his arms, legs, body, mouth, eyes, and so forth. These exploratory movements gradually develop from impressions of isolated parts into a concept of an integrated whole. As the child grows in stature, there is a continual changing of the body image. The body image concept is a fluid one even in adult life. It must be different when one is wearing glasses than when one is not wearing them. The purchase of a new hat necessitates some reorientation of body image. While one is driving, the automobile becomes in essence an extension of one's own body image. As we begin to develop the middle age spread, we readjust our concept of our body image to match.

The stroke, with its sudden hemiplegia, violently disrupts the patient's concept of his body image. Without attempting to cite the reasons and hypotheses which explain the phenomena, I should like to describe some of the phenomena observed. Most patients will early consider their involved side as paralyzed and useless. They tend to look at the *loss of function* rather than at what function is remaining. An occasional patient will deny the existence of an obvious hemiplegia or will fail to recognize the paralyzed extremities as his own.[6]

During the convalescent stage the patients begin to reorient their concept of body scheme. There is generally a tendency for persistence of the negative concept, that is, loss of function. Patients may have a tendency to look on themselves as crippled. There may even be continuing imperception for the extremity or a portion of it. The patient who is adapting more successfully will gradually begin to develop a concept of body image based on positive concepts. He will begin to recognize the remaining usefulness of his extremities and integrate the useful although impaired extremity into his ordinary daily activities. Continuing studies on the role of body image promise to give increasing information on the problem of retraining patients.

This attempt to survey quickly the principles of rehabilitation of patients who have hemiplegia has of necessity been superficial. The purpose is to give a blueprint of a flexible program of therapy. Details of the physical measures and additional bibliography will be found in the standard texts on physical medicine.[11,12] A careful study of the patient, his family and his social situation will give added information. Age of the patient, duration of disability and complicating medical conditions will influence the course of treatment but do not contraindicate instituting retraining therapy.

POSITIVE FINDINGS IN FUNCTIONAL NEUROPSYCHIATRIC DISORDERS

GORDON R. KAMMAN, M.D.

Saint Paul, Minnesota

CONTRARY to the belief of some physicians, there is no clear-cut dividing line between "functional" and "organic" nervous disorders. Formerly it was the custom to make the diagnosis of a "functional" disorder by exclusion, i.e., when the symptoms presented by the patient failed qualitatively or quantitatively to correspond to objective findings or to meet known diagnostic criteria. Physicians adhered to the two-valued "either-or" orientation and assumed that a given nosological entity had to be *either* "functional" *or* "organic."

Stanley Cobb[1] has pointed out that neuropsychiatric disturbances are the result of an interplay of four main categories of events: (1) genogenic or hereditary causes, (2) histogenic causes or those related to visible lesions of the tissues, (3) chemogenic causes due to ultramicroscopic (molecular) changes in tissue function and structure, and (4) psychogenic causes due to maladjustments in personal relations. To quote Cobb: "I would insist that the old dichotomies 'functional or organic,' 'mental or physical' are not only wrong but lead to bad habits of thinking because they lead to static and obsolete ideas and do not allow for modern pluralistic and dynamic ideas of matter and structure. Physiology is the basis of clinical diagnosis, and no physiologist would accept for a moment the clinical jargon that uses the word 'functional' to denote 'psychogenic.' Anybody who stops to think, realizes that no function is possible without an organ that is functioning and, therefore, no function takes place without structural change. Every symptom is both functional and organic. It is never a question of 'either-or'."

Lester S. King[3] considers diagnosis to be extrapolation, and he says that the process of making a diagnosis may be compared to looking at a moving picture. A motion picture reveals a definite sequence of events in which one part has some definable relation to the other parts. In making a diagnosis the physician may be compared to a movie spectator who, viewing a segment of film tries to guess the plot, predict the outcome, and name the category to which it belongs. Since diseases, like movies, fall into certain general groups, the process often is not too difficult. A veteran movie fan, seeing the middle of a picture, and seeing a cowboy, horse, some Indians and a tough looking hombre with a moustache, can usually make a pretty good guess as to the beginning of the picture which he hasn't seen and also a good guess as to the outcome which he also has not seen. In the same way, many diseases are so characteristic that the experienced physician, by observing only a brief span of its natural history, can predict the outcome as well as identify the villain.

On the other hand, some movies, like many diseases, are subtle, and the viewer must see a considerable part of it before he can hypothecate the beginning and the ending. By the same token, the physician, before he can fit a disease into a known category, must similarly have a period of observation fortified by special tests and diagnostic procedures.

In spite of the fact that there are no absolutes in the order of purely "functional" or purely "organic" diseases, there is a certain degree of polarity in the field of morbidity in general. Most diseases tend to be *predominantly* "functional" or *predominantly* "organic." As before stated, in many instances the diagnosis of a predominantly functional disorder is made on the absence of positive findings which fit into the known diagnostic categories. However, after having examined many hundreds of patients suffering from symptoms not related to any demonstrable organic lesion, I am impressed by the number of positive objective findings which emerge during the course of a neurological examination. Some of these are as follows:

Station

Although swaying or falling in the Romberg position occurs in cerebellar disease and in disorders which produce degeneration of the dorsal columns of the spinal cord (tabes dorsalis, combined sclerosis, et cetera), swaying can also occur in functional nervous disorders. However, there is a difference between the type of swaying seen

---

Read before the Ramsey County Medical Society, Saint Paul, Minnesota, November 26, 1951.

in organic disease and that seen in the psychoneuroses. In organic conditions the patient will actually fall unless he is supported by the examiner. In functional states, the patient never falls, even if he is not caught or if he is unable to reach something to steady himself. Moreover, in functional nervous disorders the swaying is of a much more bizarre and dramatic nature than it is when the manifestation is due to organic disease.

Gait

The hysterical gaits, and the gaits shown by malingerers are entirely different from those seen in organic disorders. Halting gaits, steppage gaits, grotesque limping, and bizarre and unphysiologic associated movements characterize the gait of a patient suffering from a functional nervous disorder.

Flinching and Startle Reactions

These are seen in connection with a variety of tests. When the pupillary reactions are tested with a light of moderate intensity, in many instances the patient with a functional nervous disorder will pull his head back and squeeze his eyes shut. Similarly, when the tuning fork is held close to either ear, the patient with a functional nervous disorder will pull away from it and flinch as if the sound were painful to him. These reactions are always very conspicuous by reason of their bizarre and unphysiologic nature.

An eighteen-year-old girl while playing basketball in her school gymnasium was thrown against a piece of equipment, slightly injuring her lower back. She continued to play for another fifteen or twenty minutes experiencing only slight discomfort in the back. Several hours later she reported to the school nurse that the backache was worse and that there was pain down the back of the left thigh, extending into the left calf. The pain was not aggravated by coughing, sneezing, or straining. The examination by the school physician was negative but the girl was hospitalized for physical therapy. When I saw her two weeks after the accident, she still was complaining of pain in the lower lumbar region radiating into the left calf. The neurological examination was entirely negative for organic signs. However, when the ears were tested with a tuning fork (c 128) there was a marked flinch reaction. Moreover, the *gait* was peculiar and grotesque. The patient walked on the tips of the left toes, held the left knee slightly flexed, and the knee was kept in adduction in such a manner as to produce almost a scissors gait. When pain sensation was tested with a pin, there was extreme hyperesthesia over a stocking distribution in the left lower extremity from midthigh down.

Because of these objective findings, which I consider pathognomonic of hysteria, the patient's psychic life was explored, and it was found that she was in a severe emotional conflict revolving around an adolescent love affair amid strong parental objections. She was given sodium amytal intravenously, and under its effect she abreacted and ventilated a great deal of hostility toward her parents. Physiotherapy was discontinued and the patient was given insight therapy and within two days was completely free of symptoms, and she now is in school, doing very satisfactory work.

Functional Reduplication of Deep Reflexes

This phenomenon is almost pathognomonic of a functional disorder, and I think that it relates to the startle reaction. It is difficult to describe, but, once seen, it never will be forgotten. It usually is seen when the knee jerk is elicited. Instead of a single contraction of the quadriceps femoris which appears when the patellar tendon is tapped, the patient produces a series of knee jerks in rapid succession. The reaction is totally unlike the exaggerated knee jerk seen in pyramidal tract involvement, for instead of eliciting a single reaction whose amplitude and speed are greater than those seen in normal knee jerks, the stimulus elicits a *series* of jerks. There also is what has been referred to as the "anticipatory knee jerk." A normal or organically abnormal knee jerk can be purely reflex and can be elicited in the spinal animal which has neither psyche nor consciousness. At the same time it is possible for a nervous patient to have a knee jerk just before the patellar tendon is tapped with the percussion hammer. This relates to what I have referred to as "functional reduplication" of the knee jerk, which merely indicates that the patient has anticipated the stimulus and has jerked his knee. It is the difference between the knee jerk of physiology and the "person jerking the knee" of psychobiology. It is quite clear that such a performance must necessarily be the result of a previous experience with the test, coupled with certain personal emotional attitudes and relations to it as representing general tension and fear of the examination.

Sometimes responses are accompanied by jumping of the entire body. The same thing often happens when the Achilles reflex is tested. It also may occur with the testing of other deep reflexes.

Incomplete Reactions

These are best described as more or less half-hearted attempts to carry out the commands of the examiner. For instance, when the patient is told to close his eyes tightly, he does not close them tightly. He closes them only partly, and he then opens them after having kept them partly closed for only a second or two. Another incomplete reaction is failure on the part of the patient to follow the examiner's finger when the extra-ocular movements are being tested. While the test is being performed, the patient will keep his eyes on the examiner rather than follow the examiner's finger. If he does follow the examiner's finger, he does not keep watching it but will follow the finger only part way and then return his gaze to the face of the examiner or to some other point. Rough testing of the visual fields often elicits signs that are characteristic of a functional nervous disorder. In the first place, during the confrontation test the patient will not keep his gaze fixed on the stationary reference point (usually the examiner's nose). He will watch the examiner's fingers, and sometimes it is impossible to get him to avoid doing this. Secondly, the field patterns themselves may show the typical "gun barrel" or "tubular" configuration characteristic of hysteria. If the fields are mapped on a tangent screen and then on an ordinary perimeter, in hysterical patients they will be the same size on the screen as they are on the perimeter card. This is a demonstrably objective sign of hysteria—a purely functional nervous disorder.

Another incomplete reaction is in the finger-nose test. When the patient is asked to extend his arms in the horizontal position, close his eyes, and then touch his nose, he does so in an incomplete and half-hearted manner. Furthermore, the patient frequently will display an ataxia which is all out of proportion to any known organic condition, i.e., he will touch his forehead with his index finger, or he will miss his head completely and point way past the ear opposite the hand which he is using. Furthermore, he usually will hit the same spot on successive attempts, while the patient with an organic ataxia will hit different areas. It will be noted that the past-pointing always occurs on the side of the head opposite from the hand which is being used in the test. Similar incomplete reactions are found in the heel-to-knee test.

Functional Sensory Patterns

The well-known glove and stocking anesthesia need not be discussed here. The "yes" and "no" test for sensation are well-known evidences of a hysterical disturbance. Shifting areas of anesthesia, areas of anesthesia that correspond to psychological boundaries rather than to anatomical boundaries, peculiar dissociations which are anatomically and physiologically impossible, and a variety of other sensory responses are characteristic of the functional nervous disorders.

Therefore, it is readily seen that the diagnosis of certain functional nervous disorders can be made upon positive neurological findings, and the examiner will not have to rely upon the exclusion of findings suggesting organic neurological disease.

It is interesting to speculate as to the dynamics of these positive findings exhibited by patients suffering from functional nervous disorders. I believe that the most important factor is anxiety. We know that anxiety is present in all the psychoneuroses, although it need not always be manifest. Witness the "belle indifference" of the hysteric. Here the anxiety is not overt, but it plays its part in the unconscious life of the patient.

It is not difficult to see how overt anxiety accounts for flinching and startle reactions, and how it produces the functional reduplication of deep tendon reflexes as well as the anticipatory knee jerk. However, when the anxiety is latent, one must delve into the psychodynamics of the process in order to understand the mechanism.

Grinker[2] concluded that "repression and inhibition, which are basic principles in psychoanalysis and neurology, respectively, are dynamically identical." Both repression and inhibition indicate a negative factor, in that a certain level of activity is abandoned, and a positive factor, which results from or is permitted by the shift of activity from one portion of the nervous system to another. "In the evolutionary (phylogenetic) process and

HEMORRHAGE IN THE RECTUS MUSCLE

HAROLD H. JOFFE, M.D., and DONALD J. VAN RYZIN, M.D.

Duluth, Minnesota

HEMORRHAGE into the rectus muscle and/or sheath is an established clinical entity with a definite symptomatology and physical findings. Its chief significance lies in that it is most often indistinguishable from an acute intra-abdominal condition.[1,2,6,10,11,14,17]

At this institution, two such cases were recently encountered. A summary of the cases and a review of the literature on the subject is presented.

Case Reports

Case 1.—A sixty-two-year-old machinist, one week prior to admission, experienced the gradual onset of a constant dragging pain in the right lower quadrant. The pain was occasionally sharp in character with no relation to food or exercise and remained localized. There was no fever, chills, diarrhea, constipation, food intolerance, back pain or dysuria. The stools and urine were normal in color.

On the evening of May 26, 1951, he was seen at home because the pain became more intense. The following morning the pain had not subsided and the patient was admitted to the hospital.

Physical examination revealed a well developed and well nourished male in no acute distress. The chest was clear to auscultation and percussion. The respirations were 16 and the pulse 80 per minute. The temperature was 98.6 degrees. The heart was not enlarged, the tones and rhythm were good, and no murmurs were heard. The blood pressure was 140/90. There was tenderness, rebound tenderness, rigidity and guarding in the lower portion of the right rectus muscle. Rectal examination revealed right-sided tenderness.

The red blood cell count was 4,660,000 with 13.5 grams of hemoglobin. The white blood cell count was 8,200 with 76 per cent segmented neutrophiles. The platelet count was 234,000 with a normal clotting and bleeding time. The prothrombin activity was likewise normal.

An exploratory laparotomy was performed, using a right rectus incision. A hematoma was found, which dissected up and down the rectus sheath on the right side. A visible bleeding vessel was clamped and tied. The amount of blood was neither measured nor estimated. The peritoneal cavity was entered and found to be normal, but an appendectomy was performed.

Histopathologic studies revealed complete obliteration of the appendiceal lumen by old fibrous tissue with no evidence of an inflammatory process. The material from the rectus muscle was made up entirely of blood clot with no evidence of muscle tissue.

The patient made an uneventful recovery.

Case 2.—A sixty-nine-year-old male had apparently fallen at home and sustained multiple bruises of the face, left elbow and right chest and was admitted to the hospital on August 2, 1949. The patient had had no complaints a few days before when he visited his physician for parenteral liver which he had been taking since June of 1948 when a diagnosis of pernicious anemia was made.

On admission, the abdomen was tense but no bowel sounds were audible. There was generalized abdominal tenderness and rigidity, most marked in the right lower quadrant. The hands and feet were pale and cold. The rectal temperature was 102 degrees. The pulse was rapid and feeble with a blood pressure of 100/70. The chest was clear and the neurological examination was negative. An electrocardiogram showed a right ventricular strain with right axis deviation. A portable flat plate of the abdomen was not too satisfactory but did reveal dilatation of the colon and questionable dilatation of a few loops of small bowel in the central portion of the abdomen. No fractures could be demonstrated.

The hemoglobin was 14 grams. The white blood cell count was 4,600 with 70 per cent neutrophiles. The urine showed a trace of albumin and a 4-plus sugar.

An exploratory laparotomy was performed approximately five hours after admission. A large extraperitoneal hematoma was found with a hemorrhage in the rectus muscle estimated at about 750 cc. There was no intraperitoneal bleeding.

In spite of a transfusion and adequate intravenous fluids, the patient went rapidly downhill with a shock-like picture and expired the following morning.

A necropsy examination revealed the following essential findings:

1. Diffuse infiltration of the abdominal wall with approximately 500 cc. of clotted blood in the right lower quadrant.
2. Extensive atelectasis of both lungs.
3. Severe mesenteric, mediastinal and retroperitoneal edema.

Death was due to traumatic shock.

Etiology

There is no single specific etiologic factor in this condition. The following general classification is widely accepted:[2,3,5,6,12,13,16,17,20]

1. Those with normal musculature and blood vessels.
   (a) Direct and indirect trauma.
   (b) Pendulous abdomen.
2. Those with disease or attenuation of muscles.

From the Department of Pathology, Saint Luke's Hospital, Duluth, Minnesota.

(a) During pregnancy, labor or puerperium.
(b) Debilitating diseases such as: typhoid and typhus fever, influenza, tetanus and blood dyscrasias.
(c) Vascular disease.

The effect of direct trauma such as a blow or fall is easily understood. Spontaneous or idiopathic hemorrhage has been reported to occur as the result of light exercise, jumping, riding, turning in bed, lifting, sneezing, coughing, vomiting and obstipation.[1,2,5,10,13,17,19]

In a collective review[17] of 100 cases in the literature, only 4 per cent occurred in the colored race. The ratio of women to men was 3:1. The ages ranged from seventeen to eighty-three with an average age of 46.8 years. The decades ten to thirty accounted for 14 per cent; thirty to fifty for 37 per cent; fifty to seventy for 32 per cent; seventy to ninety for 7 per cent, and in ten cases the age was not stated. In the same review, direct trauma accounted for 19 per cent and those associated with pregnancy for 22 per cent. Six cases occurred during the course of such diseases as influenza, typhoid fever and blood dyscrasia. Spontaneous or idiopathic hemorrhage accounted for 53 per cent of cases. A collective series[19] of 127 cases appearing in the literature up to 1923 disclosed that 107 (84.2 per cent) occurred in young males following exercise in whom the musculature and vascular system were normal. In a review[15] of fourteen cases occurring in women, the majority were multipara and all but one were over thirty-five years of age.

Pathogenesis

The anatomical differences of the rectus muscle and aponeurotic sheaths in the lower half of the abdominal wall account for the greater incidence of vascular rupture and hemorrhage in this location.[2,3,4,11,16,17,18] The lower third of the muscle is the most powerful portion and undegoes greater changes in length. The extramuscular branches of the vessels are likewise longer to compensate for the excessive change in length.[4] The sheath of the rectus, formed by the aponeuroses of the obliqui and transversalis muscles, passes in front of the muscle below the level of the semilunar line of Douglas. The muscle is thus separated from the peritoneum only by the thin transversalis fascia on which lies the inferior epigastric artery and its anastomoses with the descending branch of the superior epigastric artery (Figs. 1 and 2). The bleeding thus primarily occurs between the muscle and posterior sheath above the semilunar line of Douglas and between the muscle and peritoneum below this fold.[2] The hemorrhage is usually unilateral and below the level of the umbilicus.[2,17] In a collective review of 100 cases[17] the hemorrhage occurred in the right lower quadrant in forty-seven and on the left side in twenty-two cases. The right upper quadrant was the site of predilection in nine and the left upper in seven cases.

Symptoms and Diagnosis

The symptoms are essentially those of an intra-abdominal condition with abdominal pain, tenderness, rigidity, nausea, vomiting, fever, leukocytosis, ecchymosis and a palpable mass.[1,2,6,8,14,16,17] The most common and earliest symptom is pain which is usually severe and sudden in onset but may be mild for several days. In a review[17] of 100 cases in the literature, abdominal pain was present in all but three and those patients were comatosed from the onset. Tenderness is usually quite marked and was either localized or generalized in 71 per cent of cases. Abdominal rigidity, either localized or diffuse, was recorded in 59 per cent. Nausea and vomiting occurred in 23 and 15 per cent respectively. The temperature ranged from 97 to 102 degrees with an average 99.5 degrees. The white blood cell count averaged 11,600 with a high of 18,600 and predominance of neutrophils. Ecchymosis is usually a late sign and occurred in 21 per cent of cases. A palpable mass occurred in 78 per cent of cases. In no case was there an abnormal platelet count, bleeding or coagulation time.

The symptoms so closely simulate an intra-abdominal process that an incorrect diagnosis will invariably be made if this condition is not kept in mind. A careful history is essential and the onset of abdominal pain following injury or exertion, no matter how slight, should make one suspicious of a hematoma.[17] The presence of ecchymosis is of diagnostic importance but is usually a late manifestation. The two pathognomonic signs of considerable diagnostic value are: (1) a non-movable palpable mass when strain is placed on the abdominal musculature,[2,8,17] and (2) the absence of rigidity and tenderness in the abdominal wall adjacent to the palpable mass.[14,16]

The incidence of a correct preoperative diagnosis is relatively low. In a combined review, totaling 187 cases[5,7,13,17] in which a diagnosis was stated, a correct diagnosis was made in only twenty-one (10.7 per cent) of the cases. This condition is confused with a wide variety of both intra- and extraperitoneal processes, such as appendicitis, ovarian cyst and tumor, ectopic pregnancy, hernias of various sorts, mesenteric thrombosis, intestinal obstruction, gall-bladder disease, leiomyoma of the uterus, hydronephrosis, ruptured viscus, tumor of the abdominal wall, tetanus and the more rare conditions of gumma, actinomyocosis and tuberculosis.[3,5,9,17]

Treatment

Spontaneous recovery undoubtedly occurs.[2] The symptoms are so often indistinguishable from that of an intra-abdominal condition and the fact that bleeding tends to recur, makes an exploratory laparotomy the procedure of choice.[2,17] The prognosis in general is favorable but carries a certain mortality in elderly and debilitated individuals with an over-all mortality of 4 per cent in a collective review of 100 cases.[17]

Conclusions

1. The symptoms in both cases simulated a intra-abdominal condition.
2. The etiology in the first case was repeated trauma to the lower abdominal wall from the operation of a lathe. An uneventful recovery followed an exploratory laparotomy with ligation of a bleeding vessel.
3. The fall in the second case was undoubtedly the etiologic factor. Death in this case was the result of traumatic shock. The exploratory laparotomy added insult to injury and there was apparently a recurrence of bleeding.
4. A review of the literature is presented.

THE LUMBO-DORSAL FASCIA AND CHRONIC BACKACHE

R. J. DITTRICH, M.D.
Duluth, Minnesota

RECENT clinical observations have revealed additional information on abnormalities of the lumbo-dorsal fascia in individuals with back disability. The anatomical derangements of the fascia and contiguous structures, combined with the resulting physiologic disorders, appear to provide a relationship which clarifies the clinical features and simplifies treatment. In addition, an explanation has become available for a variety of clinical pictures affecting upper portions of the body.

Anatomical Considerations

In the lumbar region, the lumbo-dorsal fascia consists of a dorsal and a ventral layer, enclosing the sacrospinalis muscle. The dorsal layer is attached to the spinous processes and the ventral layer to the transverse processes of the vertebrae. In the sacral region, only the dorsal layer is present, attached medially to the spinous processes of the vertebrae and laterally to the sacrum.

In the angle formed by the dorsal and ventral layers of the fascia, fat tissue is located, overlying the lateral portion of the sacrospinalis muscle. In the sacral region a similar relationship is provided in that the fat lobules are situated between the fascia dorsally and the sacrospinalis muscle ventrally. The fat tissue at these sites represents portions of the "basic fat pattern" described by Copeman and Ackerman.[1] Although the basic fat pattern is said to be a constant feature, in two instances no fat tissue was found in the lumbar region.

The latissimus dorsi muscle is of importance for the reason that a portion of its aponeurosis of origin is attached to the lumbo-dorsal fascia.[5] It is also stated that "although the fascia becomes considerably thinner after it ceases to be the aponeurosis of the latissimus, it usually still contains distinct tendinous slips."[7] There is reason to believe that these tendinous prolongations extend over the dorsal surface of the lumbo-dorsal fascia throughout the lumbar and sacral regions.

Whereas earlier reports[2,3,4] have considered the entire extent of the basic fat pattern as sources of painful impulses, more recent studies on structural abnormalities have revealed a marked predilection for injuries of the fascia at two sites: the midsacral paraspinal region, and the midlumbar region over the lateral portion of the sacrospinalis muscle. The vulnerability of the former site is explainable by the attachment of a portion of the gluteus maximus, the latter by the origin of a portion of the latissimus dorsi muscle. For practical clinical purposes, these two sites of the fascia merit most attention.

The principal pathologic changes seen at operation consist of scar formation between the lumbodorsal fascia and the subfascial fat. The fascia, at the site of injury, may be thickened but is more often thin and distended. In three instances, a complete defect was present in the fascia, about 4 to 5 millimeters in diameter but not occupied by protruding fat tissue as described by Copeman and Ackerman. In two cases in which the injury was three to four weeks old, the fascia was dark red in color and irregularly torn.

Under normal conditions, the subfascial fat is free from the fascia and presents the characteristic yellowish color of fat tissue elsewhere. After the fascia has been traumatized by partial or complete tears, with subsequent healing the subfascial tissue shows a grayish-white color and is frequently attached to the ventral aspect of the fascia. Microscopically, prolongations of fibrous tissue can be seen extending for a considerable depth from the fascia into the fat tissue layer which has become extensively fibrosed.

With recognition of this form of abnormality, it becomes necessary to modify earlier descriptions of pathologic change, consisting of herniation and edema of subfascial fat. The impression is gained that edema of fat lobules is a secondary effect produced reflexly by the pain impulses arising elsewhere. Nevertheless, removal of such tissues, as it was carried out in the earlier stages of this investigation, has provided significant and lasting relief of pain. Complete herniations, as described by Copeman and Ackerman, have been found in only one case.

The mechanism of pain production is explained by the anatomic changes. The subfascial fat, evidently arising from the sacrospinalis muscle, seems to serve the same purpose as bursae in other locations. Traction on the fat lobules, which are well supplied with nerves and blood vessels, causes pain, as has been repeatedly demonstrated at operation. When the fat tissue becomes fibrosed and attached to the ventral aspect of the lumbo-dorsal fascia, traction on the fat lobules is more or less continuous. Both the traction and the resulting pain are aggravated by motion of the body.

Physiologic Aspects

Telalgic phenomena (referred pain and referred tenderness) are noted in practically all cases of injury to deep somatic structures. Although our knowledge of these effects is incomplete, a few well-defined principles have been established and found to be of practical importance in the evaluation of painful syndromes.

Referred pain is considered as misinterpretation by the central nervous system. It is initiated and abolished almost simultaneously with the onset and elimination of pain impulses at the primary source of the pain, or trigger-point. Referred tenderness is believed to be due to deposit of metabolites in the affected tissues. This process requires a longer period of time, usually a matter of several hours, for development after the onset of noxious stimuli and also for subsidence after cessation of the irritation. Both of these phenomena may occur in any portion of the sclerotome—a term used by Inman and Saunders[6] to denote the distribution of sensation from a spinal nerve root to deep somatic structures. Likewise both are limited to the extent of the sclerotome in which the impulses arise, although contralateral reference is a common observation, the distribution corresponding approximately to that found on the injured side of the body.

The skin is less frequently involved in cases of injury to skeletal structures. The dermatomic supply varies considerably from the sclerotomic distribution. When sensory disorders of the skin develop, they present varying degrees of hypoesthesia, even anesthesia, of the annular or "glove and stocking" type. Sensory disorders of this kind are not uncommon although they are rarely mentioned by the patient unless they become marked in degree.

When a painful lesion occurs in the lumbo-dorsal fascia in the midsacral paraspinal region, it lies within the sclerotome of the first sacral nerve. When the midlumbar region over the lateral portion of the sacrospinalis muscle is the site of an injury, the pain is experienced within the sclerotome of the second lumbar nerve or, rarely, the third lumbar. Identification of the sclerotomes related to these sites was made from the pain charts of Inman and Saunders.[6]

Following observations in two patients[2] in whom pain in the upper portions of the back was relieved by correction of the disability in the lower part of the back, it was subsequently established that this is a very common association. The mechanism involves the latissimus dorsi muscle which is in close anatomical relationship with the lumbo-dorsal fascia, particularly in the midlumbar region. With irritation of the tendinous prolongations of the aponeurosis of origin of this muscle, referred phenomena are transmitted upward within the sclerotomes of the sixth, seventh and eighth cervical nerves which supply numerous structures in the upper part of the body.

Clinical Features

With knowledge of the anatomic lesions of fat, fascia and muscle, together with application of accepted principles of referred phenomena, it is considered possible to evaluate the majority of cases of back disability quickly and accurately. The diagnosis is made from the usual history given by the patient, the description and location of the pain by the patient and the areas of hyperalgesia determined by palpation. Verification of the trigger-point is then obtained by injection of local anesthetic. Roentgenographic examination is necessary for identification or exclusion of organic disease of the bones and joints.

Classification of the various pain complexes affecting the back and the extremities can be made most clearly on an anatomical basis—the site of origin of the pain together with identification of the afferent nerve supply to the structures from which the pain arises.

The Midsacral (First Sacral Nerve) Syndrome.—When this is found in isolated form, the complaint of the patient is pain in the lower part of the back, the buttock and the lateral and posterior aspects of the thigh. Sometimes the pain is also noted in the outer part of the leg and foot. On examination, the chief finding is a diffuse tenderness in the lower two-thirds of the buttock. The trigger-point is almost invariably to be found in the paraspinal region of the third sacral vertebra.

Tenderness at the latter point may be moderate or marked in intensity, with or without radiation of the pain to other portions of the sclerotome. It may on the other hand, be elicited only on heavy pressure. Frequently a nodular mass of soft tissue can be palpated and identified as the source of the pain. The suspected lesion is verified by diagnostic injection of a local anesthetic.

The midsacral paraspinal region is apparently also the location from which pain may be referred to the coccyx, to produce the clinical picture of coccygodynia.[4]

The Midlumbar (Second Lumbar Nerve) Syndrome.—In this the chief complaint is pain in the lower part of the back, located in the lower lumbar, the upper sacral and the sacroiliac regions. Referred pain to the lower extremity, when present, is located in the groin and the adductor region of the thigh. Tenderness may be elicited at either of these areas, more commonly in the lumbar and sacral regions. The trigger-point is to be found in the midlumbar region over the lateral portion of the sacrospinalis muscle. This is substantiated by injection of local anesthetic into the subfascial tissues at the latter point.

The Latissimus Dorsi (Sixth, Seventh and Eighth Cervical Nerve) Syndrome.—Attention was called to this structure by statements of patients that they were relieved of pain in the upper portions of the body following operations in the lumbar and sacral regions.[2] The symptom-complex, developing apparently from painful irritation of the tendinous slips of origin from the lumbodorsal fascia, may present a wide variety of manifestations, subjective and objective, throughout the entire extent of the latissimus dorsi, the scapular region, shoulder, upper extremity, neck and chest. The more common complaints of the patient are pain and weakness in the scapular region and the shoulder. Tenderness is found frequently in those locations. The trigger-point is located at the site of injury of the lumbodorsal fascia in the lumbar and sacral regions. Anesthetization of this must be carried out in the superfical layers of the fascia, by interruption of the painful impulses arising in those portions of the latissimus dorsi muscle.

Headache as a symptom related to low back pain has been described in a group of seven cases.[3] Since then it has been found to occur as a common manifestation associated with disabilities due to fat and fascial lesions in the lower part of the back. The impulses arising in the tendinous fibers of origin of the latissimus dorsi muscle produce referred pain and referred tenderness in those portions of the paraspinal muscles which are innervated by the sixth, seventh and eighth cervical nerves. If it is accepted that pain and spasm of those muscles at the base of the neck are capable of producing the pain which is interpreted as headache, then it is explainable as a referred pain.

Combined Syndromes.—While each one of the individual syndromes may occur in the isolated and uncomplicated form, in many instances various combinations are found in the same patient. This is readily understandable when it is considered that the tendinous prolongations of the aponeurosis of the latissimus dorsi muscle may extend distally over the entire lumbodorsal fascia. Any injury of the fascia would be likely to include also some damage to the fibers of the tendon attached to it. Under those conditions two different streams of impulses are set up as referred phenomena: one to the second lumbar or first sacral nerve field, the other to the sclerotomes of the sixth, seventh and eighth cervical nerves. When the combination consists of the first sacral and the latissimus dorsi syndromes, the manifestations in the upper parts of the body are relatively mild in degree. The more serious types of clinical pictures are derived from a combination of the second lumbar and the latissimus dorsi syndromes. Finally, the three syndromes may be combined in the same patient.

Treatment

The indications for treatment were clarified with the discovery of the more definite pathologic changes. Recognition of the predilection for two sites of injury simplified the problem. It became obvious that only surgical measures could be employed with expectation of relief.

The technique is similar for the sacral and the lumbar regions. Under local anesthesia of the skin, a transverse incision is made over the trigger-point. The lumbo-dorsal fascia is exposed by freeing the subcutaneous fat. The fascia is incised vertically. The subfascial tissues, if adherent, are dissected from the ventral aspect of the fascia and removed. It is difficult to formulate any rule regarding the extent of resection of the fat tissues. It has become the practice to remove the layer of subfascial tissue which is obviously fibrosed, and to leave the normal fat tissue intact. Caution is necessary to avoid injury to the sacrospinalis muscle. The fascia is usually approximated with sutures, leaving an adequate opening for a soft rubber drain to be inserted into the operative field. The drain is left in place for five to seven days. Discharge of sero-sanguinous fluid continues usually for three to four weeks until the sinus is healed. If drainage is inadequate, the accumulation of bloody fluid becomes troublesome and will require evacuation.

In some cases the fascia is too thin to permit suturing; the results appear to be fully as satisfactory as in the cases in which suturing can be successfully carried out.

In cases of isolated latissimus dorsi syndrome, the incision is carried down to the fascia, the tendinous fibers of the aponeurosis are resected transversely, bleeding points are ligated and the incision is closed. A small drain is inserted for a period of twenty-four to forty-eight hours.

When the latissimus dorsi syndrome occurs in combination with either or both of the other syndromes, it requires no special attention. It appears, from the clinical results, that these fibers form part of the anatomical derangement of the fascia and any abnormality which involves these elements is simultaneously corrected.

Depending on the nature and the extent of the operative procedure, patients may leave the hospital one to three days after the operation.

Since the previous report on ten cases,[2] operations have been performed on fourteen additional patients. The type of disorder and the results in these may be classified as follows:

Midsacral syndrome—three cases—complete relief.

Midlumbar syndrome—one case—complete relief.

Latissimus dorsi syndrome—two cases—complete relief.

Midsacral and latissimus dorsi syndromes—two cases—complete relief in one; in the other, incomplete relief due to adherent, painful scar.

Midlumbar and latissimus dorsi syndromes—one case—complete relief.

Three syndromes combined—five cases. In three of these, operation was carried out in the midsacral and midlumbar regions at the same time, with complete relief in all; in one, complete relief was obtained by two separate operations; in one, partial relief was obtained, but patient refused further treatment; result is considered a failure.

Comments

From an analysis of this group of patients, several features are of sufficient importance to require emphasis. In all cases the operation was performed at one or both sites of the lower part of the back which are considered particularly vulnerable to injury. In four cases, operation was performed at both sites; in one of the latter it was bilateral. Distinct pathologic changes were found in the lumbo-dorsal fascia and the subfascial tissues in all instances except those in which the clinical picture was that of the latissimus dorsi syndrome. Clinical manifestations in the upper portions of the body, representing the latissimus dorsi syndrome, were present in ten of the fourteen patients. These were relieved in all instances except one in which additional treatment could not be carried out. Chronic head pain in six cases and attacks of dizziness in two were eliminated. Relief of disability is usually prompt so that the outcome can be determined with reasonable accuracy within a few days. Depending on the nature of the work, patients may resume such activity in one to six weeks after operation. "Complete relief" as used here, enabled the patient to return to his former, or similar, types of work, with little or no handicap.

Summary

A review is made of fourteen cases of low back pain treated surgically.

The anatomical lesions consisted of scar formation between the lumbo-dorsal fascia and subfascial fat at one, or both, of two sites in the lower part of the back: the midsacral paraspinal region and the midlumbar region over the lateral portion of the sacrospinalis muscle. The initial injury is probably a tear of the fascia produced by muscle action.

The physiologic disturbances which result from these lesions consist of referred phenomena—pain and tenderness. Knowledge of the mechanism of these processes is essential for proper evaluation of the clinical manifestations.

Clinically, three different syndromes can be recognized: the midsacral or first sacral nerve, syndrome; the midlumbar, or second lumbar nerve, syndrome; the latissimus dorsi syndrome, in which the clinical picture is dominated by manifestations within the sclerotomes of the sixth, seventh and eighth cervical nerves. Each of these syndromes may appear in isolated form. Combinations of two, or all three, syndromes in the same patient are more common.

Surgical treatment, consisting of correction of the structural changes, has yielded results which are highly satisfactory.

FUNCTIONAL NEUROPSYCHIATRIC DISORDERS

(Continued from Page 143)

in biological learning (ontogenetic) the shift is upward. In the devolutionary process of disease either functional or morphological, the shift is downward and is termed regressive." Therefore, when we are psychologically repressed, we are neurologically inhibited. Psychological repression can be and probably always is accompanied by neurological inhibition.

I believe that the "incomplete" reactions which have been described are due to repression and inhibition, which are the result of either overt or latent anxiety.

Conclusion

1. There is no clear-cut dividing line between "functional" and "organic" nervous diseases.

2. However, most disorders are either predominantly "functional" or predominantly "organic."

3. The diagnosis of a predominantly functional nervous disorder can be made on the presence of objective signs.

4. Some of these signs are described.

THE MINNESOTA PROGRAM FOR THE CONTROL OF BRUCELLOSIS

RALPH L. WEST, D.V.M.
Saint Paul, Minnesota

THE control of brucellosis in domestic animals has been of major concern to the State Live Stock Sanitary Board for more than thirty years. Progress at first was slow, but with the increasing realization by the livestock industry of the tremendous economic loss caused by this disease, and with the knowledge that the disease is transmissible to human beings and is now a public health problem, it has been possible to steadily increase the tempo of the eradication program. Popular demand for the eradication of this disease was particularly stimulated by action taken in recent years by the health departments in certain municipalities, serving notice on producers of dairy products, that after a certain date, milk and cream products, to be sold within their respective municipalities, must originate from herds free from brucellosis. In order to maintain their market, dairymen now realize they must get their house in order and are demanding that brucellosis of cattle be eradicated as rapidly as possible.

Livestock owners and livestock sanitarians realize that it is impossible to eradicate brucellosis from dairy herds unless it is eradicated from all cattle, including beef herds in the areas where dairy herds are maintained. Because of the tremendous movement of cattle in the United States from areas where beef cattle are raised, to the middle west where they are finished for beef, and because these feeding areas are usually in close proximity and often on the same farms where dairy herds are maintained, it is very necessary that the disease control officials of all states where dairying is a large project require that importation of livestock into their respective states be free from this disease. This in turn has resulted in a demand by breeders in the beef-raising states, for the elimination of bovine brucellosis, not only to reduce direct financial losses caused by the disease in their own herds, but to protect the market for feeding cattle in the midwest farming states. There has thus developed a nationwide movement for the eradication of brucellosis from the domestic animals of this country.

Minnesota has been in the forefront in this effort to eradicate this serious disease of domestic animals and human beings for many years. In 1939, the State Legislature enacted a law to provide for the eradication of brucellosis from cattle under the Area Plan, based on a similar plan which had proven so successful in the eradication of bovine tuberculosis. A number of states have enacted similar laws. The Minnesota law has been amended slightly since its original enactment, and it is believed that at the present time it provides for the most practical, orderly and systematic plan for the eradication of brucellosis of any such law in the United States. The amendments since the original law was passed have been made to adapt the law to the peculiarities of brucellosis which naturally differ in some respects from tuberculosis.

Excellent progress was made in extending the Area Plan of control after it was enacted until the advent of World War II. During the war and the unsettled conditions which followed and still exist, numerous factors, including the tremendous increase in the value of livestock and the shortage of veterinarians, have tended to delay the eradication program.

Another factor also entered the picture in 1942 which has actually delayed the eradication program, although, if properly interpreted and used, it can be of great value. I am referring to the vaccination of cattle against brucellosis, which was recommended as an adjunct to other control measures by the Bureau of Animal Industry of the United States Department of Agriculture in December of 1941. The Bureau of Animal Industry, which had developed the vaccine recommended and still in use, has emphasized at all times that this product was to be used as a supplementary procedure only, and could not in itself bring about satisfactory eradication. Nevertheless, advantage was taken of the announcement of a successful vaccine by commercial interests producing and selling the product, as well as by some segments of the livestock industry and cer-

Read at the Minnesota Public Health Conference, Minneapolis, Minnesota, September 28, 1951.

Dr. West is secretary and executive officer of the Minnesota Live Stock Sanitary Board.

tain veterinarians seeking an easy and painless method of eradicating the disease. The farm journals for several years carried misleading advertisements and article after article by uninformed persons making unjustified claims as to the value of the vaccine and the unreasonableness of the regulations requiring restraint or disposal of infected animals. Much confusion ensued and for some ten years has resulted in a definite setback to the nationwide efforts to eradicate this disease. Only during the last few years has it become generally recognized that the recommendations of the Bureau of Animal Industry, when the vaccine was first introduced, were sound and that the use of vaccination was an adjunct to other control measures. If used in this manner, it can be and is of great value, and is used extensively in the program in this state.

During the period of confusion above mentioned, there was a definite loss of ground in some states in the control of brucellosis. I am proud to report that the program in Minnesota has progressed steadily although rather slowly during the war years. Furthermore, we are today in a position to increase the program for eradication as rapidly as funds are provided by the legislature without materially changing our laws, regulations or procedures.

As above stated, the eradication of brucellosis is the goal in this state, and our program is based primarily on the Area Plan. Briefly, this plan consists in applying the agglutination blood test to all cattle in a county; the proper disposal of reactors, the quarantine of infected herds, the prevention of the importation of infected animals, and the systematic retesting until the disease has been eradicated.

The Uniform Methods and Rules of the Bureau of Animal Industry, United States Department af Agriculture, and the rules and regulations of the Live Stock Sanitary Board provide that when a test of all cattle in a county reveals the incidence of infection to be less than 1 per cent and the infected animals are found in less than 5 per cent of the herds, the county may be declared a Modified Certified Brucellosis-Free Area for a period of three years. Such declaration, however, does not complete the program. All infected and suspect herds must be retested at frequent intervals until all infected herds have passed three consecutive negative tests and until any herds in which infection is disclosed or suspected because of clinical evidence have been tested and the status of such herds determined. At the end of the three-year period of certification, the entire county is again retested and if the incidence is found sufficiently low, the county is recertified.

In order to put this plan into effect, it is necessary under the law for 67 per cent of the cattle owners to petition the Live Stock Sanitary Board. There are now thirty-six of the eighty-seven counties which have adopted the plan, and twenty-three of those counties have been declared Modified Certified Bang's Disease-Free Areas.

Progress in the area control of Bang's disease has been accelerated during the last three years by the adoption of the so-called ABR or ring test of milk and cream. This test is again a measure to supplement other procedures, and with our present knowledge cannot be satisfactorily used as a substitute. Here, again, there is grave danger that confusion may develop due to placing unjustified reliance on this measure to the exclusion of other methods of diagnosis which have proved so satisfactory in the control program to date. Where properly used, it not only allows sanitary officials to do a better and quicker job of eradication, but reduces the cost of such procedures to some extent. The role the ring test should play, in my opinion, is to discover new centers of infection which may occur from time to time in any area where the control program is in progress, due to various causes, more often than not to violations of quarantines or illegal importations. The test is not sufficiently accurate to constitute a means of officially determining the status of a herd or an individual animal, and if used in such a manner, only disappointment will result and consequently delay in the eradication procedure.

The State of Minnesota has not confined its efforts in the control of brucellosis to the eradication program under the Area Plan. Provisions have been made whereby any cattle owner may receive credit through certification of his herd, if at his own expense he eradicates and maintains his herd free from brucellosis. Also regulations have been in effect for many years requiring that cattle imported into the state must be tested and found free from the disease.

In 1945 the State Legislature enacted a law whereby all cattle over six months of age, except steers, before being sold or offered for sale for any purpose excepting for immediate slaughter or consignment to a public stockyards, must be tested and found free from Bang's disease, with two exceptions. These exceptions were cattle located in Modified Certified Bang's Disease-Free areas and cattle owned by the seller since birth. The theory on which these exceptions were based was, first, that all infected herds in counties which have adopted the Area Plan are presumed to be under quarantine, and no cattle can legally be removed therefrom except under permit from the Live Stock Sanitary Board, and, second, that cattle raisers should not be required to conduct the test before selling such cattle provided they could not be resold by dealers and traders after purchase, except for immediate slaughter. These exceptions were, however, abused in many instances, and the 1951 Legislature amended the law to delete these two exceptions and also to provide means whereby cattle legally and officially vaccinated might be sold in accordance with the rules and regulations of the Live Stock Sanitary Board without a Bang's disease test. The 1951 law is now in effect. Rules and regulations have been adopted by the Board and it is hoped that the provisions providing for the sale of vaccinates will be practical. It surely will be, if we have the co-operation of the livestock industry and the practicing veterinarians of the state on whom we must depend for its efficient operation.

Because of the warning given by certain municipalities, particularly the City of Chicago, that after a specified date only milk and milk products produced by brucellosis-free cattle may be sold within the municipality, the Minnesota Live Stock Breeders Association and the Minnesota Farm Bureau conferred with Governor Youngdahl in regard to the urgent need of expediting the eradication program in Minnesota. Governor Youngdahl appointed an advisory committee on brucellosis. This committee included representatives from all producing agencies and others interested in the eradication of the disease, including representatives of the State Department of Health and the State Live Stock Sanitary Board. A legislative program was prepared by this committee. One of the principal recommendations was an increased appropriation for the purpose of extending the area program to the entire state within the next few years. The Live Stock Sanitary Board prepared an estimate of the funds needed for the next biennium to carry out the first two years of this program. A special appropriation bill was introduced in both the House and Senate. The State Senate passed the bill unanimously, but it failed of passage in the Appropriations Committee of the House. It was killed in that committee. It is evident that satisfactory progress towards this statewide program cannot be made during the present biennium. Every effort will be made to use the funds now available to the best advantage and to extend the work as rapidly as possible, but if the entire state is to be placed under an eradication program within the deadline set by the City of Chicago and some other municipalities, it will be essential that the next legislature take action to materially increase the funds available. Their failure to do so in the 1951 session, while a serious setback to the program, need not be fatal if the legislature in 1953 will provide sufficient funds. Veterinary personnel is steadily increasing, the demand of the livestock producers is insistent, and it is believed fully possible to extend the work if only funds are made available.

Records of the State Department of Health indicate that approximately 85 to 95 per cent of the cases of brucellosis in human beings in Minnesota are caused by brucella abortus or the type of brucella organisms derived from cattle. There is, however, a material number of cases caused by brucella suis and brucella melitensis, both of which in Minnesota are caused by exposure to infected swine. Our organized control program at the present is confined to cattle. The Live Stock Sanitary Board has now under consideration the adoption of regulations for the control of brucellosis in swine based on recommendations of the United States Livestock Sanitary Association. It is not believed that brucellosis in swine is now as prevalent as the disease in cattle, nor is it as difficult to eradicate. It is possible that in the near future some additional legislation may be required, but it does not seem advisable to request such legislation until initial steps are taken through regulations to provide for certified brucellosis-free herds of breeding swine. It is hoped that this program will be in effect within a very short time.

President's Letter

THROUGH ORGANIZATION TO SERVICE

A very significant indentification card has undoubtedly been delivered to you by this time—your membership certificate from the Minnesota State Medical Association, which also indicates your inclusion in the ranks of your local medical society.

In recent years there have been varying evaluations of organized medicine, appraisals so heated that oftentimes we have used substitute phraseology for "organized medicine," to blunt the criticism directed against us on that basis. The term organized medicine, twisted into a definition of bigotry, self-interest, and monopoly, by the proponents of government health insurance, nearly met the fate of permanent identification with this description.

However, through the national education campaign, the campaigns conducted by state and county medical societies and a doctor-to-patient informational exchange, the public has been swerved from a hasty acceptance of the propaganda against the organizations of the medical profession.

In justifying organized medicine to the public, we have, ourselves, come to a clearer understanding of the purposes and ideals of the three-level organizational structure of medicine and a greater appreciation of the facilities it affords for furthering medical standards and protecting public and profession alike from health-profiteers.

Each level of membership—county, state and national—as you know, offers unique advantages to the physician: not only is his position with the public enhanced by the profession's official symbol of approval, but he is afforded a myriad of opportunities to become better able to serve his patients. Through his medical affiliation he is offered post-graduate education, the opportunity to work, with other physicians, on the scores of committees that are striving in a practical, yet progressive, fashion to solve the problems that impede the way toward increasingly better public health records. He has available, in central locations, information and literature of subjects ranging from flat feet to voluntary health insurance. He can check the efficacy of a new drug, obtain a speaker for a medical meeting, order a packet of material to help him in writing a scientific paper, sign up for an insurance policy at lower-than-individual rates, obtain assistance in legal difficulties, book an education film, receive a list of available physicians from which to choose a partner or an associate. But all these advantages and many more are familiar to you, as a member of organized medicine.

In recounting the purposes and merits of these organizations, however, we must continually bear in mind that none of the three, neither the county, nor the state, nor the American Medical Association exists as an entity unto itself. The organizations are interwoven and, although autonomous, are interdependent and, more particularly, they are dependent for their continued successful record of service upon active participation, utilization, and endorsement by every member. We cannot content ourselves with mere acceptance of the functions of medical societies—we must vigorously and consistently support and implement those functions, helping to adapt them to each new turn of events, each new challenge and demand upon the profession. You have only begun to assume your rightful reponsibilities when you pay your dues and accept the certificate of membership.

Roger L J Kennedy

President, Minnesota State Medical Association

NARCOTIC ADDICTION ON THE INCREASE

THE ALARMING INCREASE in narcotic addictions, particularly in the youth of our larger cities, should be emphasized and exposed to the full glare of publicity.

Certain facts about drug addition should be given to the public in order to know how best to attack the problem. It is perhaps not widely recognized by the profession that the smoking of marihuana cigarettes provides the start for most narcotic addicts. With youthful recklessness and the mistaken idea that to smoke this weed is smart, the misstep is taken that leads to more serious and irretrievable addiction. While the smoking of marihuana causes a form of intoxication that is harmful, discontinuance of its use is not accompanied by serious withdrawal symptoms. The most serious aspect of its use is that it so often leads to the use of heroin or morphine. In the search for new thrills (so-called), the youngster tries the sniffing of heroin and for further, more effective use, tries the intravenous administration of small doses of heroin. Habitual use leads to the requirement of larger and larger doses of this expensive narcotic which is no longer sold by druggists or prescribed by physicians but is bartered entirely by members of the underworld at exorbitant prices. The habit gets such a hold on the addict that he will do anything to obtain the drug or obtain the cash needful to buy his supply. The addict, as is well known, loses his moral sense of right and wrong, and will lie or steal or resort, in the case of the lesser percentage of girls who constitute the unfortunate group, to prostitution in order to obtain necessary funds.

According to *Today's Health* for October, 1951, in Chicago alone the State Attorney's office processed 3,126 addicts in six months. On one day recently, one-fourth of the prisoners in Cook County jail in Chicago were addicts, ninety-two under twenty-one, 108 between twenty-one and twenty-five and ninety-five over twenty-five. Admissions to the two Federal hospitals for addicts rose from 2,700 in 1949 to 4,500 in 1950. The addicts in these hospitals under twenty-one jumped from twenty-two in 1947 to 440 in 1950. Boys outnumber girls six to one.

The hold that narcotics get on their victims is difficult to imagine, and perhaps impossible to imagine for anyone not an addict. Release of the addict from the bonds of the habit is the exception rather than the rule. For this reason, prevention of the commerce in narcotics except for medicinal purposes, and of heroin for all purposes, lies in the field of national control. Physicians must aid Uncle Sam's preventive activities to the utmost. How insidious and powerful drug addiction can be is evidenced by the regrettable fact that many physicians allow themselves to become addicted to one narcotic or another, and demerol seems to be a favorite.

Punishment is and should be severe for those convicted of underground traffic in narcotics. The exposure being made in the public press of the insidious dangers accompanying the trifling with narcotics should be of value in a preventative campaign.

A NEW TECHNIQUE FOR ARTIFICIAL RESPIRATION

IN THE September 1951 number, we mentioned the undesirable features of the Schaefer and Sylvester methods of artificial respiration. With the former method, the air is forced out of the lungs and the entirely passive recoil of the chest on the relief of the pressure results in a small amount of air being inspired, while the inhalation of air, with the Sylvester method, is an active process as well as the exhalation. The disadvantage of the latter method is that the tongue has to be seized by a forceps or a safety pin and pulled forward to avoid the swallowing of the tongue. Most of us do not carry a forceps or safety-pin with us, and time is of the essence when artificial respiration is needed.

In view of the drawbacks possessed by both these methods, it is not surprising that a third method has been devised and adopted, largely through the efforts of the American Red Cross.

In 1947, the American Red Cross requested the Council of Physical Medicine of the AMA to review the problem. A committee of the Council reported that the Schaefer method taught for years by the Red Cross was inferior to other methods. As a result, the Red Cross made grants during 1948 and 1949 to evaluate various methods. After studying air exchange induced by artificial respiration in animals and human beings, it was decided that the back pressure—arm lift method used for many years in Europe, especially in Denmark and Norway, was comparatively easy to learn and perform and produced a satisfactory volume of tidal air. The military consultants in June, 1951, recommended to the armed forces that they adopt this method. In October, 1951, at a meeting of the National Research Council, at which a number of agencies such as the Red Cross, the AMA, the Army, Navy and Air Force were represented, the back pressure-arm lift method originally described by Holzer Nielsen was decided upon as being the preferable one. The standard technique, as described by the Red Cross, is as follows:

Standard Technique for the Back Pressure-Arm Lift Method of Artificial Respiration

The Standard Technique, agreed upon by a committee appointed at the meeting of agency representatives on October 2, is as follows:

(Position of the Subject)

1. Place the subject in the face down, prone position. Bend his elbows and place the hands one upon the other. Turn his face to one side, placing the cheek upon his hands.

(Position of the Operator)

2. Kneel on either the right or left knee at the head of the subject, facing him. Place the knee at the side of the subject's head close to the forearm. Place the opposite foot near the elbow. If it is more comfortable, kneel on both knees, one on either side of the subject's head. Place your hands upon the flat of the subject's back in such a way that the heels lie just below a line running between the armpits. With the tips of the thumbs just touching, spread the fingers downward and outward.

(Compression Phase)

3. Rock forward until the arms are approximately vertical and allow the weight of the upper part of your body to exert slow, steady, even pressure downward upon the hands. This forces air out of the lungs. Your elbows should be kept straight and the pressure exerted almost directly downward on the back.

(Expansion Phase)

4. Release the pressure avoiding a final thrust, and commence to rock slowly backward. Place your hands upon the subject's arms just above his elbows, and draw his arms upward and toward you. Apply just enough lift to feel resistance and tension at the subject's shoulders. Do not bend your elbows, and as you rock backward the subject's arms will be drawn toward you. Then drop the arms to the ground. This completes the full cycle. The arm lift expands the chest by pulling on the chest muscles, arching the back, and relieving the weight on the chest.

The cycle should be repeated 12 times per minute at a steady uniform rate. The compression and expansion phases should occupy about equal time, the release periods being of minimum duration.

Additional Related Directions

It is all-important that artificial respiration, when needed, be started quickly. There should be a slight inclination of the body in such way that fluid drains better from the respiratory passage. The head of the subject should be extended, not flexed forward, and the chin should not sag lest obstruction of the respiratory passages occur. A check should be made to ascertain that the tongue or foreign objects are not obstructing the passages. These aspects can be cared for when placing the subject into position or shortly thereafter, between cycles. A smooth rhythm in performing artificial respiration is desirable, but split-second timing is not essential. Shock should receive adequate attention, and the subject should remain recumbent after resuscitation until seen by a physician or until recovery seems assured.

SCIENCE TALENT SEARCH

TOO OFTEN youthful talent is not discovered, and because of a lack of financial backing the high school boy or girl with exceptional natural ability in the field of science is never able to develop his God-given gifts.

In order to discover the talented boys and girls of high school age, Science Service, a non-profit institution for popularization of science, has been established. Its trustees are nominated by the National Academy of Sciences, the National Research Council, the American Association for the Advancement of Science, the E. W. Scripps Estate and the journalistic profession. Financed by the Westinghouse Educational Foundation, it forms Science Clubs in the high schools all over the country. Through these clubs, students are urged to undertake research problems in the field of science. Each year, examinations are held and from the 300 top-ranking contestants forty are awarded trips (all expenses paid) to Washington, D. C., to take part in a five-day Science Talent Institute. They visit places of scientific interest in our capital, meet prominent scientists, and compete for scholarships awarded by the Westinghouse Educational Foundation. Although the scholarships total but $11,000, nearly half going to the winner and runner-up in the contest, to be among the 300 top-ranking contestants serves as a recommendation for admission to a college.

The record shows that of 400 chosen during the past ten years, 178 have earned undergraduate degrees, forty-seven Masters and twenty-three M.D., Ph.D., or D.Sc. degrees. At least eighty have full-time positions as astronomers, mathematicians, chemists, engineers, physicists or physicians in research centers or nationally known industries.

Science Service is located at 1719 N Street N. W., Washington 6, D. C.

HENNEPIN COUNTY NEONATAL MORTALITY STUDY

During 1950, in Minnesota, 1,874 infant deaths occurred. On the basis of provisional figures, 1,893 infant deaths occurred in 1951. There are as many deaths during the first year of life as there are in the total of the next consecutive 39 years. In other words, as many babies die before reaching their first birthday as the total number of deaths that occur between the ages of one and 40 years. More than one-third of these babies die during their first day of life; more than two-thirds die during the first week of life; and three-fourths of all the deaths during the first year of life occur within the first month after birth. Less than 25 per cent of infant deaths occur between the first and twelfth month of life. Thus, any significant reduction in infant mortality must depend on a decrease in deaths during the first month of life, the so-called neonatal period. While many of these deaths are non-preventable at the present state of our medical knowledge, there are many that are considered preventable and hence the special interest in neonatal mortality.

A study of maternal deaths by the Minnesota State Medical Association in co-operation with the Department of Obstetrics of the University and the State Department of Health, was first carried out in 1941-42. It was reactivated in 1950 and is now in its second consecutive year. In 1941-42 the maternal mortality rate was 1.6 per 1,000 live births with 94 maternal deaths. On the basis of 1951 provisional statistics, the rate has dropped to 0.4 per 1,000 live births with only 32 deaths, a decrease of 75 per cent in the rate in a decade. The effectiveness of the maternal mortality study and its general acceptance is further evidenced by the fact that the Council of the State Medical Association has requested the State Health Department to continue to underwrite the study indefinitely. It is generally felt that a similar study of neonatal deaths should produce equally effective results. A state-wide neonatal study, however, presents a much more formidable problem, as almost 1,500 neonatal deaths occur annually in Minnesota. Furthermore, many clinical records in rural hospitals are scanty, laboratory facilities may be limited, and autopsies are infrequent. A state-wide study was therefore considered impractical and it was deemed advisable to establish a pilot study in one metropolitan area. After the pilot study demonstrates its value, it is planned to extend the study to Ramsey, St. Louis, and other counties and possibly to eventually make it state-wide in scope.

Hennepin County was selected for the pilot study because it is a convenient and easily accessible area, has a limited number of neonatal deaths, with fairly complete records, and has a reasonably high percentage of autopsies. Of a total of 500 annual infant deaths occurring in 15 Minneapolis hospitals, there are approximately 385 neonatal deaths or 32 per month; 43 per cent have autopsies, a total of 165 per year or 14 per month.

The Board of Directors of the Hennepin County Medical Society has approved the study and appointed the following committee:

Dr. A. Friedell, Dr. E. C. Maeder, and Dr. H. R. Ransom.

The Northwestern Pediatric Society has approved the study and appointed:

Dr. F. H. Adams, Dr. E. S. Platou, and Dr. L. F. Richdorf.

The Minneapolis Health Department has appointed:

Dr. Evelyn Hartman.

The Minneapolis Hospital Council has appointed:

Mr. Russell Nye, Superintendent, Northwestern Hospital.

And from the Medical School, University of Minnesota:

Dr. Irvine McQuarrie, Head, Department of Pediatrics.

Dr. James R. Dawson, Jr., Head, Department of Pathology.

The Committee elected Dr. L. F. Richdorf as Chairman and Dr. A. B. Rosenfield as Secretary.

The objective of the study, in general, is to reduce the preventable causes of neonatal mortality by a detailed study of each neonatal death, including management of the newborn, nursery procedures, and the adequacy of autopsies.

More specifically, the committee will:

Consider the clinical history, physical findings, and diagnosis in relation to autopsy findings.

Rate responsibility—
- Was it a pediatric or obstetric death?
- Was it preventable or non-preventable, or unclassifiable?
- Was there adequate prenatal care?
- Were there adequate hospital facilities?
- Was family, physician, or hospital at fault?
  - (a) Error in judgment or technique?
  - (b) Intercurrent disease?
  - (c) Unavoidable disaster?

Judge adequacy of records, autopsies, et cetera.

Point out inadequacies and make suggestions for reducing preventable factors by an educational program—
- (a) At Medical Society meetings.
- (b) At hospital staff meetings
- (c) Through medical bulletins and journals
- (d) Through other educational approaches.

The study will limit itself to all deaths *under twenty-eight days* of life *with autopsies,* in accordance with the generally accepted definition of "neonatal," which relates to the period of life, following delivery, of less than 28 completed days. The study will be carried out by means of specially prepared questionnaires that will be completed by the hospital librarian at the time the clinical record is compiled. A detachable tab at the top of the form will contain the name of the patient, the attending physician, and the hospital and patient code numbers so that death certificates may be cross matched. To maintain anonymity of patient, physician and hospital, however, this tab will be removed by the Minnesota Department of Health before referring the completed report to the Study Committee, leaving only a hospital code number and a patient code number on the study form.

Each hospital staff has been requested to appoint a hospital committee consisting of a pediatrician, an obstetrician, and the pathologist to supervise the completion of the study form, to return the form to the study committee, and to act as a liaison group between the hospital librarian and the Neonatal Study Committee. The possibility of employing a pediatrician-investigator to prepare the questionnaires and a summary of each death, similar to the method used in the maternal mortality study, will be considered by the committee. A member of the state-wide maternal mortality study committee, Dr. C. J. Ehrenberg, will serve as liaison member to the Hennepin County Neonatal Mortality Study Committee.

The study will begin as of January 1, 1952, and will continue during the current year. At the end of one year's study, the committee will evaluate the benefits and accomplishments of the study and will determine the future course of the study.

THE JOURNAL OF THE SAMA

For several years, there has been some talk of the desirability and need for a Students' American Medical Association. This culminated in a resolution passed by the AMA House of Delegates assembled in San Francisco in June, 1950, approving the formation of a Students' AMA and pledging the support of the AMA to the new organization. On December 28, 1950, delegates from forty-eight medical schools met at the Sheraton Hotel in Chicago in response to letters sent to the Deans of every medical school by Dr. George F. Lull, Secretary of the AMA. On the following day, December 29, 1950, the Students' AMA was launched.

The first officers elected at this Chicago meeting were: Warren R. Mullen, University of Michigan Medical School, president; Harry W. Sandberg, University of Illinois College of Medicine, vice president; David Buchanan, University of South Dakota School of Medical Sciences, treasurer. A constitution was drawn up which by March, 1951, had been ratified by forty-one component student medical societies which became charter chapters in the new organization. From the start it was evident that the AMA had no desire to dictate to the students' organization. However, three Senior Councilors to the Students' AMA, Drs. Ernest E. Irons, G. Lombard Kelly and Thomas P. Murdock, were appointed by the AMA Trustees, to serve in advisory capacities.

Last July, the Council of the SAMA decided to publish a journal for the membership of the SAMA to be known as *The Journal of the Students' American Medical Association.* The first issue appeared in January and nine issues will appear each year during the school months. Subscriptions are free to all medical students who are members of the SAMA. Efforts were made to reach every medical student in the country. If any medical student or intern has failed to receive his journal, he may fill out the form that appears on page 6 of the January issue of the *Students' JAMA* (or a similar certificate), have it countersigned either by the SAMA chapter advisor or the dean of the medical school, and send it to Students' AMA headquarters at 535 North Dearborn Street, Chicago 10, Illinois.

There is undoubtedly a need for a Students' AMA. Canada has had an active student intern organization for more than ten years. Similar organizations exist in Austria, Denmark, France, Germany, Italy, India, Netherlands, Sweden and Switzerland. It is also generally felt that there is a definite need for a SAMA journal which will contain articles of scientific and public relations value for the doctors of tomorrow.

Minnesota Medicine extends its best wishes for the success of this youngest journal of them all—*The Journal of the Students' American Medical Association.* The January issue is a credit to the students' organization.

ANTABUSE® AND BARBITURATES

Care should be taken in the administration of a barbiturate to one who is being treated with Antabuse.® While no clinical cases have been reported, in animals the effect of certain barbiturates is magnified many times by the pre-administration of Antabuse.®

HEALTH PROBLEMS IN INDIA

Communicable diseases are a major feature of health conditions in India. Smallpox, plague, cholera, typhoid, and dysentery still claim an enormous number of victims every year. Malaria is rampant throughout the region and claims over 100 million cases, with more than one million deaths every year. Tuberculosis is extremely common. While no reliable statistics are available, it has been estimated that in India alone there are two and one-half million cases, with half a million deaths every year. Another three-fourths of a million cases are estimated for Java and Madura, and so on—for other countries. The quantitative aspect of the health problems therefore presents a staggering picture. Poverty, hunger, and disease are arrayed in force against the people. In the field of tuberculosis, international assistance of WHO is being directed primarily to providing training facilities in modern methods of diagnosis and prevention. In Southeast Asia, an army of tuberculosis workers is needed, not a platoon. New training and demonstration centers, at present being opened with WHO assistance in almost all the countries of the region, are intended to point the way and to stimulate governments to concrete action on an adequate scale.—Chandra Mani, M.D., *American Journal of Public Health,* December, 1951.

Medical Economics

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

AMERICANS CONTINUE TO GET MORE AND BETTER MEDICAL CARE

The latest report of the AMA's Bureau of Medical Economic Research shows conclusively that, on the whole, the American people in 1950 received relatively more medical care for their money than they did in 1935-39. Dr. Frank Dickinson, director of the bureau, felt, however, that such a quantitative analysis could not possibly reveal the great improvements in the quality of medical care. He states: "Such tremendous strides in our health progress as the sharp reduction in the number of maternal deaths per 1,000 live births from about 5.0 in 1935-39 to less than 1.0 in 1950 and the jump in life expectancy at birth from 59.5 years in 1930 to more than 68 years in 1950 are not measured by indices of the quantity of medical care."

During the past twenty years, according to this report, the American people have spent a constant proportion of their consumer budget, roughly 4 per cent, for medical care. Dr. Dickinson explains this comparatively small proportion in this way: "The demand for medical care has been small in comparison to the demand for other consumer items. It has been small, not because people could not afford more, but because they preferred to spend their budgets in this manner. In the past one could say that the irregularity and unpredictability of medical expenses were greater deterrents to the purchase of medical care than the actual amount of expenses. Today, however, the widespread availability of hospital and medical insurance makes medical care a readily marketable item."

Medical Insurance Readily Available

The report states that the availability of hospital and medical insurance enables any particular family to approach this 4 per cent rate—the average for all families.

> "A family can purchase a typical Blue Cross-Blue Shield membership, which will pay the bulk of hospital and in-hospital medical bills for roughly 25 cents a day—the price of a package of cigarettes . . . With over half the population carrying some form of medical or hospital insurance, the small demand for medical care certainly does not mean that people do not have the money for medical care, but that they are purchasing the amount they desire."

Get More for the Money

Thus, the report continues, "with the index of the prices of medical care, including the high hospital rates, lagging behind the index of all consumer prices, they are receiving much more medical care for their money. In fact, average weekly earnings have risen so much more rapidly than the cost of medical service, *that a production worker today can buy almost twice as much medical care with a week's wages as he could in 1935-39*. And health progress has given him another dividend—more and better years in which to earn. Today, in a period of general inflation, the consumer is getting more and better medical care for the same proportion of his personal consumer expenditures."

Explaining the changes further, the report says:

> "The rise between 1945 and 1950 largely reflects wartime conditions in 1945, the tremendous increase in the number of births in the postwar years, the rapid rise in hospital room rates and the increased use of hospitals."

The report also pointed out that during the last twenty years, the physicians' share of the medical dollar dropped 12 per cent, from 31.8 cents to 28.1 cents, while the hospitals' share rose 66 per cent, from 13.9 cents to 23.1 cents. The report stressed the fact that the amount of services rendered by the average doctor was from one-third to one-half times greater in 1950 than during 1935-1939. Introduction of wonder drugs, improved transportation, increasing proportion of patients seen in the hospital and office, and other increases in technological efficiency have all contributed to this change in the over-all situation.

MEDICAL, SURGICAL INSURANCE STILL GROWS

A recent report of the Research Council for Economic Security has announced "an unprecedented growth in the activity of the commercial insurance companies in the hospital field during the past few years."

The report presents the following figures for comparison:

> "In 1939, some 1,260,000 persons were protected by group hospital insurance. By 1944, that number had grown to 8,400,000 and as of 1950 it was estimated to be 22,600,000. This is 15.1 per cent of our 1950 population. Some 75 million persons either have policies or are dependents of policy-holders who were covered by hospital insurance in 1950. Therefore, roughly 50 per cent of the population, excluding the armed forces, are estimated to have some measure of hospital insurance protection. It is estimated that the insurance companies pay from 45 to 50 per cent of the total hospital costs of their policy holders."

In the medical-surgical field, the report states that, in 1939, about 630,000 persons had cash indemnity coverage providing for medical and surgical costs. By 1944, the number had passed 5½ million and at the close of 1950, estimates placed it near 21,500,000. About 46 per cent of the total surgical and medical charges of group and individual policyholders are paid.

RENEWAL OF HEALTH PLAN FIGHT RE-EMPHASIZES HUGE COST

New agitation for enactment of compulsory federal health insurance has brought a renewed effort on the part of the medical profession and other groups to defeat any such legislation even before it gets started. A recent statement quoted in the Christian Science Monitor stresses the proposed program's huge cost: "Adoption by the United States of an all-inclusive national medical service like that in Britain would cost the federal government at least $18 billion a year, perhaps more, according to Miss Elizabeth W. Wilson, actuary and economist who has specialized in government health insurance." She reports:

> "Americans now spend approximately $10 billion yearly on both private and government medical care . . . the British health service is presently costing approximately three times the amount originally named by advocates, . . . the costs of any such system rise with the rise of salaries and the cost of materials. Inflation has boosted the cost of the British health service, and would boost the comparably sized American health service in the same way."

Compulsory Insurance Inflationary

Miss Wilson's estimate of the amount of the rise in cost over the $18 billion now forecasted by advocates of the system, is $3 billion more than a similar estimate made three years ago. That means a 20 per cent increase, she stated. "The introduction of socialized medicine would be inflationary in itself in tendency because $18 billion is approximately $8 billion more than is being spent in the United States for medical care at the present time. Unless such an added expenditure would result in the production of $8 billion more goods, the net result would be inflationary."

Miss Wilson concludes:

> "The figure of $18,000,000,000 represents about 7.5 per cent of the total annual income, whereas today the average American worker pays only about 4 per cent of his wages to medical care. Would the average workman—if he knew the actual figures—wish to nearly double his expenditure to obtain the benefits of government medicine? The Truman administration and the Federal Security Agency advocate introduction of a compulsory health insurance system which they say would be less inclusive than the British. It would cover somewhat more than 85 per cent of the population and would not include complete hospital or dental care. Certain drugs would not be free. But, experience has shown that once such a system is inaugurated, coverage is expanded to include all types of care for everyone."

JOURNAL URGES MORE IMPROVEMENT OF VOLUNTARY HEALTH PLANS

Asking the question, "what is the purpose of the medical profession, of our hospitals, and of our health insurance plans?", a recent editorial in the *Illinois Medical Journal* states that the answer is as plain as the question: "the provision of the best possible medical care to the greatest number of people." The *Journal* states:

> "In any consideration of their activities this fundamental purpose must never be lost sight of. Whenever other aims, other purposes are allowed to assume greater importance than the provision of the best possible medical care, we invite just criticism and, still more seriously, we invite failure. In spite of the fact that health insurance plans deal primarily with economic problems, we must always organize and develop, criticize, re-examine and reorganize these plans in answer to the question—'Do they help to assure the best possible medical care?'"

(Continued on Page 178)

◆ Reports and Announcements ◆

AMERICAN ACADEMY OF GENERAL PRACTICE

The American Academy of General Practice will hold its fourth Annual Assembly at Atlantic City, March 24-27, 1952.

The scientific program has been carefully planned so that the Scientific Exhibits will be an integral part of the formal teaching program. An array of outstanding teachers will take part in the program.

All AMA members are invited to attend. A registration fee of $5.00 will be required from non-members.

Hotel reservations may be made through the A.A.G.P. Housing Bureau, 16 Central Pier, Atlantic City, New Jersey.

AMERICAN COLLEGE OF CHEST PHYSICIANS

The eighteenth annual meeting of the American College of Chest Physicians will be held at the Congress Hotel, Chicago, Illinois, June 5 through 8. A scientific program covering all recent developments in the treatment of heart and lung diseases is being arranged.

The Board of Examiners of the American College of Chest Physicians announces that the next oral and written examinations for fellowship will be held in Chicago on June 5. Candidates for fellowship in the College who wish to take the examinations should contact the Executive Secretary, American College of Chest Physicians, 112 East Chestnut Street, Chicago 11, Illinois.

Dr. John F. Briggs, Saint Paul, is regent of the College for the district, and Dr. Herman J. Moersch, Rochester, serves as governor of the College for Minnesota. Officers of the Minnesota Chapter are Dr. Gustaf A. Hedberg, Nopeming, president, and Dr. Arthur M. Olsen, Rochester, secretary-treasurer. Dr. Jay Arthur Myers, Minneapolis, is editor-in-chief of the College journal, *Diseases of the Chest.*

AMERICAN CONGRESS OF PHYSICAL MEDICINE

The thirtieth annual scientific and clinical session of the American Congress of Physical Medicine will be held on August 25, 26, 27, 28 and 29 at the Roosevelt Hotel, New York, N. Y. Scientific and clinical sessions will be given on the days of August 25, 26, 27, 28 and 29. All sessions will be open to members of the medical profession in good standing with the American Medical Association. In addition to the scientific sessions, annual instruction seminars will be held. These lectures will be open to physicians as well as to therapists who are registered with the American Registry of Physical Therapists or the American Occupational Therapy Association. Full information may be obtained by writing to the American Congress of Physical Medicine, 30 North Michigan Avenue, Chicago 2, Illinois.

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

A special meeting of the Minnesota Society of Neurology and Psychiatry was held at the Town and Country Club in Saint Paul on February 5. Dr. H. Houston Merritt, Professor of neurology, Columbia University, was the guest speaker. Dr. Merritt's subject was "Epilepsy: Its Physiological Basis and Treatment."

PHYSICIANS ART ASSOCIATION EXHIBIT

The Physicians Art Association will have an exhibit at the Minnesota State meeting this year. Ample space and arrangements are being made, thanks to the sponsorship of the State Association and the Hennepin County Medical Society. The committee urges physicians to exhibit paintings, photography, sculpture, metal work and any other art project in this great exhibit. Be sure to enter your work out of your own interest and to encourage others in this excellent type of hobby.

Write to Dr. F. A. Zinter, 600 Physicians and Surgeons Building, Minneapolis, Minnesota, for entry blanks.

CONTINUATION COURSES

Otolaryngology.—The University of Minnesota announces the eighth biennial continuation course in otolaryngology to be held June 23 through 27. This course, designed to bring to the practicing otolaryngologist the newer concepts and developments in the specialty, will be under the direction of Dr. Lawrence R. Boies and associates of the University Medical School. Dr. Fred A. Figi, Dr. Henry L. Williams and others of the Graduate School faculty will participate in the instruction. Guest lecturers will include Dr. Louis Clerf, Philadelphia; Dr. Leland Hunnicutt, Pasadena; Dr. William McNally, Montreal, and Dr. W. Wallace Morrison, New York.

The fee for this course is $50. The enrollment is limited. Application should be made at an early date to the Director, Center for Continuation Study, University of Minnesota, Minneapolis 14, Minnesota.

Proctology.—The University of Minnesota will present a continuation course in proctology at the Center for Continuation Study on April 14 to 19. The course is intended primarily for physicians engaged in general practice. All aspects of ano-rectal disease will be covered, and two half days will be devoted to operative clinics in which registrants will take an active part. The visiting faculty member of the course will be Dr. Garnet W. Ault, professor, Department of Proctology, Georgetown University School of Medicine, Washington, D. C., and the course will be presented under the direction of Dr. O. H. Wangensteen, professor and chairman, Department of Surgery, and Dr. Walter A. Fansler, clinical professor, Department of Surgery, and di-

now in parenteral form...

BANTHĪNE®
Bromide

Brand of Methantheline Bromide

for use when oral administration is difficult or impractical —when more prompt action is desired

Banthine—a true anticholinergic drug with an adequate range of safety—is now made available to the medical profession in parenteral form, for use intravenously or intramuscularly in those conditions characterized by nausea and vomiting, when oral medication cannot be retained and when a prompt action is desirable.

Through its anticholinergic effects, Banthine inhibits excess vagal stimulation and controls hypermotility.

In Peptic Ulcer —the value of the oral form of Banthine is now well established. However, edema in the ulcer area may indicate parenteral Banthine until the healing processes have reduced the edema.

In Pancreatitis —it has been found that parenteral Banthine relieves pain, effects a fall in blood amylase and produces a general improvement in the patient's condition.

In Visceral Spasm —it inhibits motility of the gastrointestinal and urinary tracts.

Parenteral BANTHĪNE is supplied in serum-type ampuls containing 50 mg. of Banthine powder. Adult dosage is generally the same as with Banthine tablets.

Woman's Auxiliary

AUXILIARY PRAISED BY PRESIDENT KENNEDY

State board members of the Woman's Auxiliary were urged to continue assisting democracy to "keep its house in order," at the annual mid-winter board meeting, held January 16 at the Curtis Hotel in Minneapolis.

Dr. R. L. J. Kennedy, president of the Minnesota State Medical Association, asked auxiliary members to help with "washing out the dirty linen created by political propaganda-rakers, sweeping out of office the bureaucrats unqualified to conduct this country's affairs, and dusting off our cherished ideals of freedom and personal initiative."

Dr. Kennedy praised the auxiliary for its excellent cooperation and aid to the medical profession and called for continued efforts to keep the issue of socialized medicine from gaining a foothold in America. There is to be no slackening of individual effort in the national education campaign being conducted by the American Medical Association and by state and county medical societies, Dr. Kennedy pointed out.

Speaking at the luncheon, Dr. Kennedy cited President Truman's recent appointment of a commission to study health needs and a proposal to provide free hospitalization for all persons over sixty-five, regardless of their ability to pay, as examples of devious means of obtaining government control of the nation's health.

"As long as the public knows the value of its liberty, rights and responsibilities, we need never fear that socialism will gain entry," he said. "Protecting our own threshold—the right of the individual to choose the medical care he wants—is vital, but we must continue to interpret this right and this freedom in its context of all American freedoms. We know that when the public loses control over its health care, then it has begun to lose control over every other field of human thought and endeavor. We can't let that happen here and we won't."

Countering the charge that doctors are against everything and for nothing except the status quo, Dr. Kennedy said: "We are for the status quo, insofar as that is interpreted to mean the present framework for medical practice, research and education. . . ." He noted that that framework cannot work except by a constant changing and state of flux.

Regarding medicine's so-called "negative attitude," Dr. Kennedy said:

"We are hard at work at far more progressive programs than the socializers, with all their Utopian dreaming, ever visualized. We are, for example, working very hard on a problem that medical science, through its progress, has created for itself: geriatrics, the problem of an aging population in a world that is not yet geared to making the most of the 20 bonus years that medical advancements have added to the average life span. We are concerned with the correlated problem of proper care of the chronically ill. We're troubled over civil defense and trying, through leadership in our ranks, to help awaken a tragically dormant populace. We're interested in improving and enlarging medical schools, without sacrificing the excellence we have strived so hard to gain."

Auxiliary President Reports

Beginning the morning Board meeting, Mrs. F. P. Moersch, president of the State Auxiliary, reported on the Conference of State Presidents and Presidents-Elect which was held in Chicago last November, stating that "all but three states and territorial auxiliaries were represented," and with nearly 130 women attending.

Mrs. Moersch summarized for auxiliary members each of the important panel discussions which were presented at the meeting, including which states were represented on each panel, what topics were discussed, and what conclusions were drawn. Mrs. Moersch represented the Minnesota Auxiliary on the panel on Health Days, speaking on "The Meaning and Objectives of Health Days."

The excellent attendance at this meeting, Mrs. Moersch felt, proves the familiar saying that "coming together is a beginning; working together is growth; staying together is progress." She quoted Mrs. Eusden, national president-elect, who stated: "Today, state presidents and presidents-elect believe attendance at this conference is one of the duties that they assume when taking office."

Board Hears Reports

Also during the morning Board meeting, reports of various committee chairmen and county representatives present were heard. Members were urged to subscribe to the Bulletin, and *Today's Health,* and to work to collect surplus medical supplies, to be informed about legislative matters, to promote Health Days, to continue to plan interesting and informative programs. County presidents, or a representative from the county, reported on activities of their auxiliaries since the fall conference, revealing much progress and continued hard work on the part of medical auxiliaries throughout the state.

LEGISLATIVE REPORT SENT TO COUNTIES

Mrs. H. F. R. Plass

A summary of the medical profession's official position on all important national legislative matters has been sent to all county auxiliary presidents and legislative chairmen.

In Memoriam

E. SYDNEY BOLEYN

Dr. E. Sydney Boleyn, for over fifty years a practitioner at Stillwater before his retirement five years ago, died on December 23, 1951, at the age of 87. For years he had been active in the affairs of Washington County Medical Society and of the Minnesota State Medical Association. He was secretary-treasurer of his county society for about 40 years and served as vice president of the state association at one time.

Born on shipboard under the British flag, May 1, 1864, Dr. Boleyn was educated in England before coming to this country in 1886. He obtained his medical degree at the University of Minnesota in 1894. After interning three years at St. Barnabas Hospital, Minneapolis, he spent 15 months more in medical training at the State Penitentiary in Stillwater before locating in Stillwater for private practice.

On December 2, 1907, he was married to Helen Businger who survives him.

Even after his retirement from practice, Dr. Boleyn maintained his interest in medical affairs and was a regular attendant at state and county medical meetings as long as his health permitted.

At a County Officers Medical Conference held in St. Paul in 1940, Dr. Boleyn remarked on the longevity which had characterized his family and stated that his mother was living at the age of 104 at that time and his father was about 10 years older. Both were residing in India at that time, his father being a retired civil service employe of the British Government. The oldest relatives he knew of were an uncle who had lived to be 127 and an aunt 124.

AXEL E. HEDBACK

Dr. Axel E. Hedback, on the editorial board of the *Journal Lancet* beginning in 1920, the editor of *Modern Medicine* from 1933 to 1939 and lately editor of *Geriatrics*, died December 31, 1951.

He was born at Karlstad, Sweden, April 21, 1874. His preliminary education was obtained at New Richmond, Wisconsin, and he received his M.D. at the University of Minnesota in 1897. A year's internship was spent at the State Penitentiary in Stillwater. Postgraduate study was taken at Harvard, Johns Hopkins and the University of Vienna.

Dr. Hedback was active in civic affairs and took part in raising funds for the new central YMCA building in Minneapolis. He was a onetime member of the Minneapolis charter commission and was a member of the Minnesota State Board of Health from 1919 to 1923. He was president of the Hennepin County Medical Society in 1928.

Dr. Hedback is survived by his wife, Gladys W. Hedback, a son, John William Hedback of Chicago and three daughters, Mrs. Dwaine Lindberg of Minneapolis; Mrs. Don O. Lampland and Mrs. David Paul Keefe of St. Paul.

JOHN H. MILLS

Word has been received of the death of Dr. John M. Mills on October 14, 1951, in Portland, Oregon; he was formerly a fellow in medicine of the Mayo Foundation.

Dr. Mills was born May 19, 1902, at Liverpool, England. He received the degree of M.D. in 1933 from the University of Chicago and interned at the Presbyterian Hospital, Chicago, from May, 1932, to October, 1933.

Dr. Mills entered the Mayo Foundation as a fellow in medicine on January 1, 1934; he received the degree of M.S. in Medicine in 1936 from the University of Minnesota and left the Foundation on January 1, 1937, at which time he went to Tacoma, Washington, to practice general medicine. During the next several years he practiced general medicine at Lakeland, Florida; was instructor in medicine at the University of Maryland; practiced general medicine at Chicago and was instructor in medicine at Northwestern University. He joined the staff of the Rockwood Clinic in Spokane, Washington, in June, 1941, and more recently was chief of medicine of the Veterans Administration Hospital at Marquam Hill, Portland, Oregon. He became a lieutenant colonel while on active service, A.U.S., and served successively at Letterman General Hospital, San Francisco, Kennedy General Hospital, Memphis, Tennessee, and Cushing General Hospital, Framingham, Massachusetts. After his separation from the service he resumed his work at the Veterans Administration Hospital at Marquam Hill, Portland, Oregon.

Dr. Mills was a fellow of the American College of Physicians, and a member of the American Medical Association, Alphi Chi Sigma, Sigma Xi, Phi Rho Sigma and Alpha Omega Alpha.

RUSSELL WRIGHT MORSE

Dr. Russell W. Morse, well-known radiologist of Minneapolis, died December 29, 1951, in Panama City, Florida.

He was born in Minneapolis May 24, 1894, and attended Minneapolis Central High School. He received the degrees of B.S. and B.M. from the University of Minnesota in 1917 and M.D. in 1920. He interned the following year at the University Hospital from 1920 to 1924.

Dr. Morse practiced in Minneapolis from 1920 to 1924 when he moved to New York. In 1932 he returned to Minneapolis where he practiced until his death. He was roentgenologist at St. Barnabas Hospital and clinical

RUSSELL WRIGHT MORSE

(Continued from Page 166)

assistant professor of radiology at the University of Minnesota School of Medicine.

Dr. Morse was a past president of the Minneapolis Academy of Medicine, a member of the Hennepin County Medical Society of which he was president in 1940, a member of the New York Academy of Medicine, the Radiological Society of North America, the American College of Radiology and the Minnesota Radiological Society.

Surviving are his wife, Elizabeth, a daughter, Melva; and a son Russell, both of Bozeman, Montana. Two stepsons, Lyman and Robert Tifft both of Edina also survive him.

Dr. Morse was a member of the Minneapolis Club and for many years was active in musical organizations in Minneapolis. An accomplished cellist he often appeared in concerts with amateur musical groups. His untimely death was the result of an anemia incurred by exposure to X-ray radiation.

J. SPENCE REID

Word has been received of the death of Dr. J. Spence Reid, former fellow in surgery of the Mayo Foundation, on November 29, 1951, at Toronto, Ontario.

Dr. Reid was born December 26, 1893, at Tillsonburg, Ontario, and received the degree of M.B. in 1920 from the University of Toronto after which he practiced medicine at Tillsonburg for one year. He entered the Mayo Foundation as a fellow in surgery on January 1, 1922. From October 1, 1924, to January 1, 1926, he was first assistant in surgery and he left the Mayo Foundation on April 1, 1926, to practice surgery in Toronto.

Dr. Reid was a fellow of the Royal College of Surgeons of Canada and a member of the Toronto Academy of Medicine, the Ontario Medical Association, Alpha Kappa Kappa, and Alpha Omega Alpha.

Dr. Roger L. J. Kennedy, Rochester, president of the Minnesota State Medical Association, was the principal speaker at the annual mid-winter board meeting of the medical association's Woman's Auxiliary in Minneapolis on January 16.

* * *

It was announced on January 10 that **Dr. R. L. Baird** had become associated in practice with **Dr. F. W. Franchere** at Lake Crystal. Dr. Baird, a graduate of the University of Colorado School of Medicine, was a resident physician at St. Luke's Hospital, Saint Paul, prior to joining Dr. Franchere.

* * *

Dr. David S. Thorsen, Saint Paul, was guest speaker at a meeting of the Saint Paul Association for Mentally Retarded Children on January 9.

* * *

Among those attending a continuation course in pediatrics at the University of Minnesota early in January was **Dr. Clayton E. J. Nelson** of Albert Lea.

* * *

Dr. Henry E. Michelson, Minneapolis, was recently elected an honorary member of the Austrian Dermatological Society.

* * *

At the annual meeting of the Itasca County Board on January 8, **Dr. M. J. McKenna** of Grand Rapids was named county health officer.

* * *

Dr. Gaylord W. Anderson, director of the University of Minnesota School of Public Health, has been appointed to the board of editors of the newly revised magazine, *Public Health Reports.* The magazine is an expanded version of the weekly journal of the same name which has been published since 1878 by the Public Health Service.

* * *

Among the featured speakers at a meeting of the Probate Judges' Association at Minneapolis on January 9 and 10 were **Dr. Ralph Rossen,** Minnesota mental health commissioner, and **Dr. Nelson Bradley,** superintendent of the Willmar State Hospital.

* * *

Dr. W. L. Benedict, Rochester, attended the Pan-American Ophthalmology Conference in Mexico City early in January. Dr. Benedict is the executive secretary-treasurer of the American Academy of Opthalmology and Otolaryngology.

* * *

Dr. Clarence Siegel, Saint Paul, presented a review of tuberculosis cases at the Ramsey County Children's Preventorium during a meeting of the Minnesota Tuberculosis Nurses Council at the preventorium on January 15.

* * *

Lt. Col. Thomas E. Dredge, Minneapolis, is now serving in Korea as senior advisor to the South Korean army medical service. He is helping to build a medical corps modeled along American lines.

When the war started, many Korean medical students were unable to complete their education, so an army medical school was established. Thus far it has graduated 130 students. A similar training program for nurses was also set up.

Dr. Dredge, a son of **Dr. and Mrs. H. P. Dredge** of Sandstone, is a graduate of the University of Minnesota Medical School. During World War II he was chief of medicine at Air Force hospitals at Miami, Florida, and at Veterans Administration Hospital, Brecksville, Ohio. He joined the United States military advisory group to the Republic of Korea in November, 1950.

* * *

Dr. J. Paul Person, Albert Lea, was a guest speaker at a meeting at Albert Lea on January 10 of the Freeborn County Relatives and Friends of the Mentally Retarded. Dr. Person's topic was "Physiological Aspects of Retardations."

* * *

Dr. George E. Moore, of the Department of Surgery at the University of Minnesota, was the guest speaker at a meeting of the Woman's Club at Hutchinson on January 10. Dr. Moore, who has been recognized for his work with fluorescine dye and radioactive substances in the detection of brain tumors, presented a discussion of cancer.

* * *

Dr. Nels M. Strandjord, Virginia, was awarded a certificate of merit for community service at the annual banquet of the Virginia Junior Chamber of Commerce on January 15.

A one-day conference on criminal psychiatry for state hospital employes and law enforcement officials was held at the Hastings State Hospital on January 30. The conference was conducted by **Dr. William H. Haines,** psychiatrist at the Cook County Behavior Clinic, Chicago.

HOSPITAL NEWS

The following are the results of staff elections held recently at several Minnesota hospitals:

Glencoe Municipal Hospital, Glencoe.—Dr. H. H. Holm, president; Dr. H. C. Goss, secretary-treasurer.

Swedish Hospital, Minneapolis—Dr. Arthur N. Russeth, chief of staff; Dr. Nordahl Peterson, vice chief of staff; Dr. Delph T. Stromgren, secretary-treasurer.

Lutheran Hospital, Bemidji.—Dr. T. P. Groschupf, president; Dr. Charles Vandersluis, vice president; Dr. Harry A. Palmer, secretary-treasurer.

St. Joseph's Hospital, Brainerd.—Dr. John A. Thabes, Jr., chief of staff; Dr. R. A. Beise, vice chief of staff; Dr. A. M. Mulligan, secretary-treasurer.

Eitel Hospital, Minneapolis.—Dr. A. C. Olson, president; Dr. R. D. Thielen, vice president; Dr. Allan J. Blake, secretary-treasurer.

* * *

Le Sueur County became associated with nine other counties in the ownership of the **Southwestern Minnesota Sanatorium** at Worthington early in January when the board of commissioners paid almost $8,000 as a first half installment on a one-tenth equity in the institution. Increased cost of patient care and increased numbers of tuberculosis patients were given as reasons for the step. The cost of maintaining patients in state institutions had grown so much that the county commissioners decided to join the sanatorium group as an economy move.

Other counties who are part owners of the sanatorium are Blue Earth, Lincoln, Murray, Pipestone, Watonwan, Jackson, Cottonwood, Lyons and Nobles.

BLUE CROSS-BLUE SHIELD PLANS

In administering the Blue Shield Claims Department, rejection of claims involving previously known conditions has been the most difficult single feature. Claims rejected as previously known conditions require that questionnaires be sent to both the attending physician and the subscriber. Relationships with subscribers and doctors are not infrequently disturbed by the rejection of such claims. For these reasons, the previously known condition clauses of sixty Blue Shield plans in continental United States have been reviewed, and the results of this study appear to be of importance in any future consideration of this general problem.

Of the contracts examined, forty-one were service and nineteen were indemnity. Among the sixty contracts reviewed, four made no mention of pre-existing conditions and sixteen had no restrictions or limitations regarding such conditions. Further analysis revealed that of the ten largest plans in the country, three have indemnity contracts, and six have waiting periods for pre-existing conditions, while 4 place no limitation on such diseases.

Of the forty plans which limit benefits for previously existing conditions, thirteen exclude such benefits permanently—that is, they never pay benefits for conditions which antedated the effective date of the contract. The remaining twenty-seven contracts exclude benefits for pre-existing conditions for periods varying from six to eighteen months. Eighteen of these plans have a waiting period of eleven to eighteen months, four have a waiting period of ten months, and only five have a waiting period of six to nine months. Minnesota Blue Shield with its 10-month waiting period is more liberal or has a shorter waiting period than the majority of the plans in this survey which have some restrictions regarding pre-exitsing conditions.

As a result of this review, Minnesota Blue Shield has revised its subscriber and physician foreknowledge letters, this being the third revision during the past year. The entire system of informing both the physician and the subscriber of the rejection of claims has also been remodeled. In the newly adopted method, one letter is used for the six reasons for rejection which means "no contract is in effect" with the specific reason checked. Each of the remaining causes for rejection has a special letter to both the subscriber and doctor, each using as much as possible the exact language of the contract pertaining to that reason for rejection. This new method has been so fashioned as to save employees' time, inform both subscriber and physician regarding the contract, and improve subscriber and physician relationship.

During December, 1951, 7,279 claims were paid by Blue Shield and these claims costs amounted to $254,812.95. Minnesota Medical Service Inc. during this year 1951 provided medical-surgical-obstetrical care to approximately 88,000 Blue Shield subscribers. Payments to doctors during 1951 for their services amounted to approximately $3,095,000.

Since Blue Shield was incorporated four years ago, approximately 182,000 claims have been paid for Blue

Shield subscribers and doctors have received approximately $6,662,000 for their services rendered to these Blue Shield subscribers.

During the third quarter of 1951, Blue Shield Plans throughout the nation gained a total of 1,403,063 new members. The increase in membership was comprised of approximately 423,725 subscribers and 979,338 dependents. As of September 30, 1951 membership in the seventy-seven approved Blue Shield plans totaled 20,279,725 and consisted of approximately 8,416,086 subscribers and 11,863,639 dependents.

Approximately 166,500 Blue Cross subscribers received hospital care during 1951 totaling approximately $12,500,000.

Since Blue Cross was organized in Minnesota in 1933, approximately 1,230,000 subscribers received hospital care with benefits totaling approximately $63,800,000.

During the third quarter of 1951, Blue Cross Plans throughout the nation gained a total of 468,918 new members. The increase in membership was comprised of 167,427 subscribers and 301,491 dependents. As of September 30, 1951, membership in the 88 approved Blue Cross plans totaled 40,888,535 and consisted of 17,126,007 subscribers and 23,762,528 dependents.

Non-Group Enrollment Opens

As of Friday, January 11, on the Blue Cross-Blue Shield "Dinner at the Adams" radio show via WCCO, Cedric Adams again began a series of direct appeals for non-group enrollment. In other words, *NON-GROUP ENROLLMENT IS AGAIN OPEN UNTIL FURTHER NOTICE!*

SPATIAL VECTOR ELECTROCARDIOGRAPHY; CLINICAL ELECTROCARDIOGRAPHIC INTERPRETATION. By Robert P. Grant, M.D., National Heart Institute, Bethesda, Md., and E. Harvey Estes, Jr., M.D., U. S. Naval Hospital, Bethesda, Md. 149 pages. Illus. Price $4.50. Philadelphia: Blakiston, 1951.

Spatial vector electrocardiography is assuming importance in bringing precision into the study of electrocardiography. The vector method of interpretation supersedes the empirical method of such an interpretation in a great many ways. We have, as a result, better criteria for differentiating the normal from the abnormal record. These criteria are precise and more rational. Although this volume makes no effort to be comprehensive it is an excellent and readily understandable exposition of a difficult subject. This volume will be valued by anyone interested in electrocardiography.

John F. Briggs, M.D.

ROSENAU PREVENTIVE MEDICINE AND HYGIENE. Kenneth F. Maxcy, ed. Seventh edition, New York; Appleton Century, Inc., 1951.

The first edition of this authoritative work was published in 1913 by Dr. Milton Y. Roseman, Professor of Preventive Medicine and Hygiene at the Harvard Medical School. In five subsequent editions, the work was brought up to date in a field that has been making rapid progress during the years. His sixth edition was published in 1935.

The task of bringing out a seventh edition was accepted in 1942 by Dr. Kenneth F. Maxcy, Professor of Epidemiology, the Johns Hopkins School of Hygiene and Public Health. The war interfered with progress in the compilation of a work which necessarily required the cooperation of many specialists in the various phases of Preventive Medicine. This seventh edition will continue the publication as a valuable and authoritative source of reference.

C. B. Drake, M.D.

SURGERY OF THE OBLIQUE MUSCLES OF THE EYE. By Walter H. Fink, M.D. 350 pages with 93 illustrations. Price $8.75. St. Louis: C. V. Mosby Company, 1951.

This is an excellent book by one of our Minnesota authors. The volume is well illustrated with numerous anatomical photographs and line drawings.

Part I goes into great detail on embryology, comparative anatomy, developmental anomalies, and microscopic and gross anatomy of the superior oblique muscles. The author has made a successful attempt to be very inclusive in his coverage of the subject matter. The illustrations are particularly helpful.

Part II covers the Management of Oblique Muscle Defects. The chapter on Diagnosis contains seventy-three pages giving a very comprehensive coverage of the many tests that may be applied. To one who is less conversant with the field than the author, it is perhaps confusing to be forced to choose from so many different tests. The chapter on Surgical Technique is very lucidly illustrated and is a pleasure to read. An appended chapter on Anatomical Considerations in Operation for Retinal Detachment is well illustrated and very helpful.

M. F. Fellows, M.D.

JOURNAL URGES MORE IMPROVEMENT OF VOLUNTARY HEALTH PLANS

(Continued from Page 161)

Warns Against Negative Approach

"A negative approach to these problems is not enough," according to the *Journal*. "We cannot merely find fault with and oppose those plans of which we do not approve. We must continue to improve, expand and extend the voluntary insurance programs along with other plans to achieve the best possible medical care. Each plan, each program, each extension, and each limitation must be examined in that light."

The *Journal* emphasizes that the voluntary insurance plans are mutual efforts:

> "They are no more a way of obtaining something for nothing than is aid from the Federal Government. Every service provided through these insurance plans has to be paid for by the members of the plans, by the recipients of the services. These plans are merely means of avoiding large, unexpected, unplanned, expenses at one time and of spreading this expense over a larger number of people, for the time being, and over a number of years."

CONTINUATION COURSES

(Continued from Page 162)

rector, Division of Proctology. The remainder of the faculty will include members of the clinical staff of the University of Minnesota Medical School and the Mayo Foundation.

Surgery.—The University of Minnesota will present a continuation course in surgery on April 7 to 9. The course will be held at the Center for Continuation Study and is primarily intended for physicians engaged in general practice. The course will be concerned primarily, but not exclusively, with pediatric surgery. The guest speaker for the course will be Dr. Robert E. Gross, Ladd Professor of Children's Surgery, Harvard Medical School, and surgeon-in-chief, Children's Hospital, Boston, Massachusetts, who will also deliver the annual George E. Fahr Lecture on April 8 at 8:00 p.m. The subject of the Fahr Lecture will be "Coarctation of the Aorta." In conjunction with the continuation course, Dr. Gross will also discuss "Surgery in the Early Months of Life" and "Treatment of Certain Tumors in Childhood." The course will be under the direction of Dr. Owen H. Wangensteen, professor and head of the Department of Surgery, and he will be joined by clinical and full-time members of the staff of the University of Minnesota and the Mayo Foundation.

McLEOD COUNTY SOCIETY

Dr. Joseph Selmo, Norwood, was elected president of the McLeod County Medical Society at its annual meeting at Glencoe on January 17. Named as secretary of the organization was Dr. Kenneth H. Peterson, Hutchinson.

WASECA COUNTY SOCIETY

At the annual meeting of the Waseca County Medical Society at Waseca on January 7, Dr. S. C. G. Oeljen was elected president and Dr. S. T. Normann, vice president, both of Waseca; and Dr. George H. Olds, New Richland, secretary-treasurer.

The Balance Sheet

We are all striving mightily to set aside some portion of our income in reserve. This is not an easy task in this day of heavy taxation. Yet these reserves are important; to be used for contingencies that we cannot predict today. It's silly to be forced to stand idly aside and watch those reserves being dissipated through protracted periods of disability when you could have prevented it by the purchase of an outstanding Disability Policy.

It's only logic that indicates that your best plan of income protection is through the plan available to you through your Association.

Tomorrow may be too late—ACT NOW.

SELECTED MEDICAL FILMS

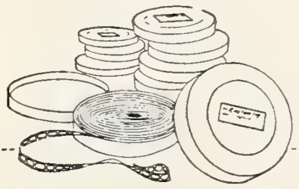
...FROM THE SQUIBB MEDICAL FILM LIBRARY

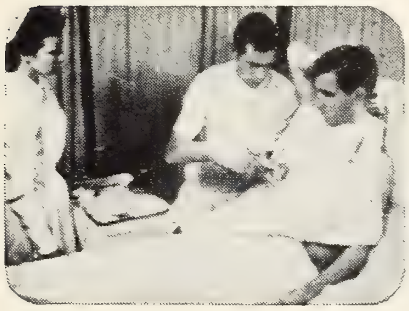
Ask Your Squibb Professional Service Representative

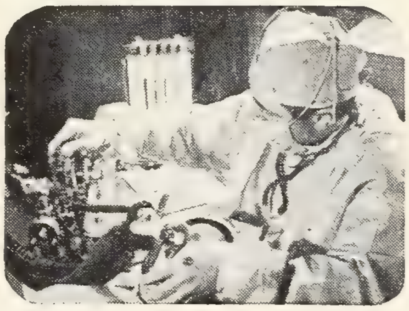
Squibb Medical Film Library offers selected motion pictures for showings at your medical group, staff meeting, or hospital—without cost or obligation.

These special films present a pictorial clinic of important medical subjects and new forms of therapy, of particular interest at medical schools, conventions, staff meetings, and to special hospital groups. Actual filming of these motion pictures was supervised by eminent medical authorities. Most films are in color, 16 mm. width, majority with sound track. Running time is from 5 to 45 minutes.

You may obtain a catalog of Squibb Medical Films from your Squibb Professional Service Representative, or by writing directly to us. Your Squibb Professional Service Representative will also obtain the films for you and handle all arrangements for the showings.







E. R. Squibb & Sons, 745 Fifth Avenue, New York 22, New York

For Your Security and Peace of Mind

A Disability Life Income Program for Eligible Members of your Profession

Lifetime Protection for both Sickness & Accidents

A SILENT PARTNER . . . Continental's Companion Policies

ACCIDENT AND CONFINING SICKNESS

Pays $ 400	Monthly Benefits first 2 years ($200 1st mo.) and
$ 300	Monthly Benefits thereafter for Life.
Pays $ 600	Additional Monthly Benefits First 3 Months for Hospital Disability.
Pays $ 7,500	Accidental Death Benefits, $12,500 Double Indemnity.
Pays $10,000	Loss of Hands, Feet or Eyes, $15,000 Double Indemnity (or)
$ 5,000	Cash, & $400 monthly first 2 years, $300 monthly thereafter. Adjusted benefits for disabilities occurring after age 60.

SPECIAL FEATURES

No Cancellation Clause,—Standard Provision 16

No Terminating Age,—Standard Provision 20

No increase in Premium,—Once Policy is Issued

Grace Period 15 Days

Non Pro-Rating,—Standard Provision 17

Non-Assessable,—No Contingent Liability

Non-Aggregate,—Previous Claims Paid do not limit Company's Liability

Unusually Complete Protection

- ★ Pays Monthly Benefits from 1st Day to Life.
- ★ Pays Benefits for both Sickness and Accident.
- ★ Pays Lifetime Benefits for Time or Specific Losses.
- ★ Pays Regular Benefits for Commercial Air Travel.
- ★ Pays Benefits for Non-Disabling Injuries.
- ★ Pays Benefits for Non-Confining Sickness.
- ★ Pays Benefits for Septic Infections.
- ★ Pays Whether or not Disability is Immediate.
- ★ Waives Premiums for Total Permanent Disability.
- ★ Renewal is guaranteed to individual active members, except for non-payment of premium, so long as the plan continues in effect for the members of your designated organization.

60% Protein

. . . . yet as delicious as any milk beverage

A mixture of milk protein concentrate, soy protein, whole egg powder, powdered sugar, and flavoring, H. P. S. Sixty provides

Protein	60%
Fat	1.5%
Carbohydrate	27%

This high protein dietary supplement is outstanding in palatability. Its biologically complete proteins are intact, hence it is not burdened by objectionable taste or odor.

H.P.S. Sixty provides 3.6 calories per gram, 102 calories per ounce.

Prepared with water according to directions (6 oz. water, 1½ oz. H.P.S. Sixty), three daily servings (three 6 oz. glasses) provide 77 Gm. of protein; prepared with skim milk, three glasses provide 96 Gm. of protein; with whole milk, 95 Gm. of protein.

Valuable for use when the protein intake must be increased by the oral route and when whole protein can be utilized, as in undernutrition, peptic ulcer, hepatitis, chronic diarrheal states, pregnancy and lactation, and following burns and other conditions which raise the protein need.

KLER-RO®

"Ulmer"

THE RESULT OF MODERN RESEARCH

Put an end to overnight soaking by using KLER-RO. In just ten minutes crusted coatings of blood and contamination are readily dissolved without affecting the sharp edges or points of surgical instruments. KLER-RO cleans instruments of the most intricate design—penetrates hard to reach parts with ease and efficiency.

Surgical linens are saved from quick discard or transformation into autoclaving wraps. Smock, apron and gown emerge from the KLER-RO solution with all evidence of blood stains removed. KLER-RO is economical. A single 2 lb. can gives you 42 gallons of full strength detergent solution.

Order KLER-RO today, or send for your trial sample. Test KLER-RO on your hardest cleaning problems and you will see why we say, "They'll Come Clean With KLER-RO."

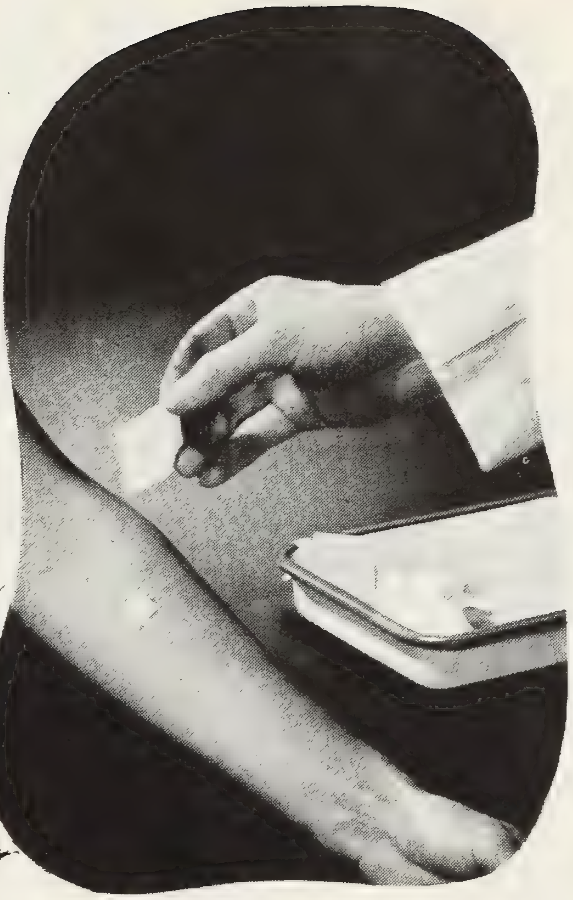
citrus is virtually

NON-ALLERGENIC



TYPICAL PATCH TEST

Over 400 infants and children from 2 weeks to 6 years of age acted as test subjects to check the incidence of sensitivity to orange juice. After 2 to 12 months' observation,* "no disturbance of bowel function (diarrhea or constipation) that could be attributed to the orange juice" was found. Also, the occurrence of regurgitation and rashes was "minimal". In the rare instances of sensitivity, care exercised by gentle reaming of juice (or the use of frozen concentrate) to avoid contamination with peel oil usually obviates the difficulty.

IN CONGESTIVE HEART FAILURE

"In severe congestive failure, our most dependable remedy is the mercurial diuretic . . . Its combination with theophylline has been a distinct advance."[1]

Salyrgan-Theophylline is a highly effective combination of a mercurial diuretic and theophylline. It may be given orally in certain cases.

Salyrgan-Theophylline is extensively employed for the treatment of cardiac and cardiorenal edema, dropsy of nephrosis and ascites of hepatic cirrhosis. The diuretic response does not "wear out," so that in most cases administration may be repeated as required for years, without loss of efficiency.

Noth,[2] for instance, in discussing a case of Pick's disease, states that the patient "has received about 450 doses of mercurial diuretics, nearly all of which were of Salyrgan given [parenterally] . . . At no time has he experienced orthopnea, nocturnal dyspnea, or episodes of dyspnea while at rest. He is still working every day as a banker . . ."

Meat and its Important Contribution of Essential Minerals

With the exception of calcium and iodine,[1] meat, as customarily consumed, makes an important contribution to the mineral needs of the American people. Its minerals include those needed in substantial amounts as well as those needed in trace amounts only.

The array of data listed below gives the approximate amounts of essential minerals provided by muscle meat when seven ounces per day are consumed.[1] The minerals include those now known to be essential components of the human organism—the skeletal framework and teeth, soft tissue structures including blood, and substances concerned in regulatory functions.

APPROXIMATE MINERAL CONTENT OF MEATS

200 Gm. (approx. 7 oz.),[1] Edible Portion (Uncooked)

	Beef Round	Lamb Leg	Pork Loin	Veal Shoulder
Minerals, total[2]	2.0 Gm.	1.8 Gm.	1.8 Gm.	2.0 Gm.
Calcium[2]	22 mg.	20 mg.	20 mg.	22 mg.
Chlorine[3]	147 mg.	136 mg.	125 mg.	147 mg.
Copper[3]	0.2 mg.	0.2 mg.	0.2 mg.	0.2 mg.
*Iodine[4] (Ohio animals)	0.02 mg.	0.03 mg.	Data not available	0.01 mg.
Iron[2]	5.8 mg.	5.4 mg.	5.0 mg.	5.8 mg.
Magnesium[3]	46 mg.	42 mg.	39 mg.	46 mg.
Phosphorus[2]	360 mg.	426 mg.	372 mg.	398 mg.
Potassium[3]	661 mg.	610 mg.	559 mg.	661 mg.
Sodium[3]	164 mg.	152 mg.	139 mg.	164 mg.
†Cobalt[5]	0.0002 mg.	———	Data not yet available	———
†Manganese[3]	0.03 mg.	0.03 mg.	0.02 mg.	0.03 mg.
†Zinc[5]	9.4 mg.	———	Data not yet available	———

*Iodine content of meat varies with the iodine content of feed of the animals.
†Needed in trace amounts only.

The average values for iron, phosphorus, and copper of the four kinds of meat shown constitute about 46, 25, and 100 per cent, respectively, of the National Research Council's recommended daily allowances for adults, and the average values for chlorine, potassium, and sodium constitute about 14, 63, and 16 per cent, respectively, of the estimated daily adult needs, as based on mineral balance studies.[6] Although no specific information is available on the quantitative needs for cobalt, magnesium, manganese, and zinc, nutrition information would suggest that the amounts reported above have nutritional importance or significance.

In addition to its notable content of essential minerals, meat also furnishes large amounts of biologically complete protein and important amounts of vitamin B complex, which includes biotin, choline, folic acid, inositol, niacin, pantothenic acid, pyridoxine, riboflavin, thiamine, and vitamin B_{12}. On the basis of its rich contribution of nutritional essentials, meat well deserves its prominent place in the daily diet of the American people, the world's best-nourished people.

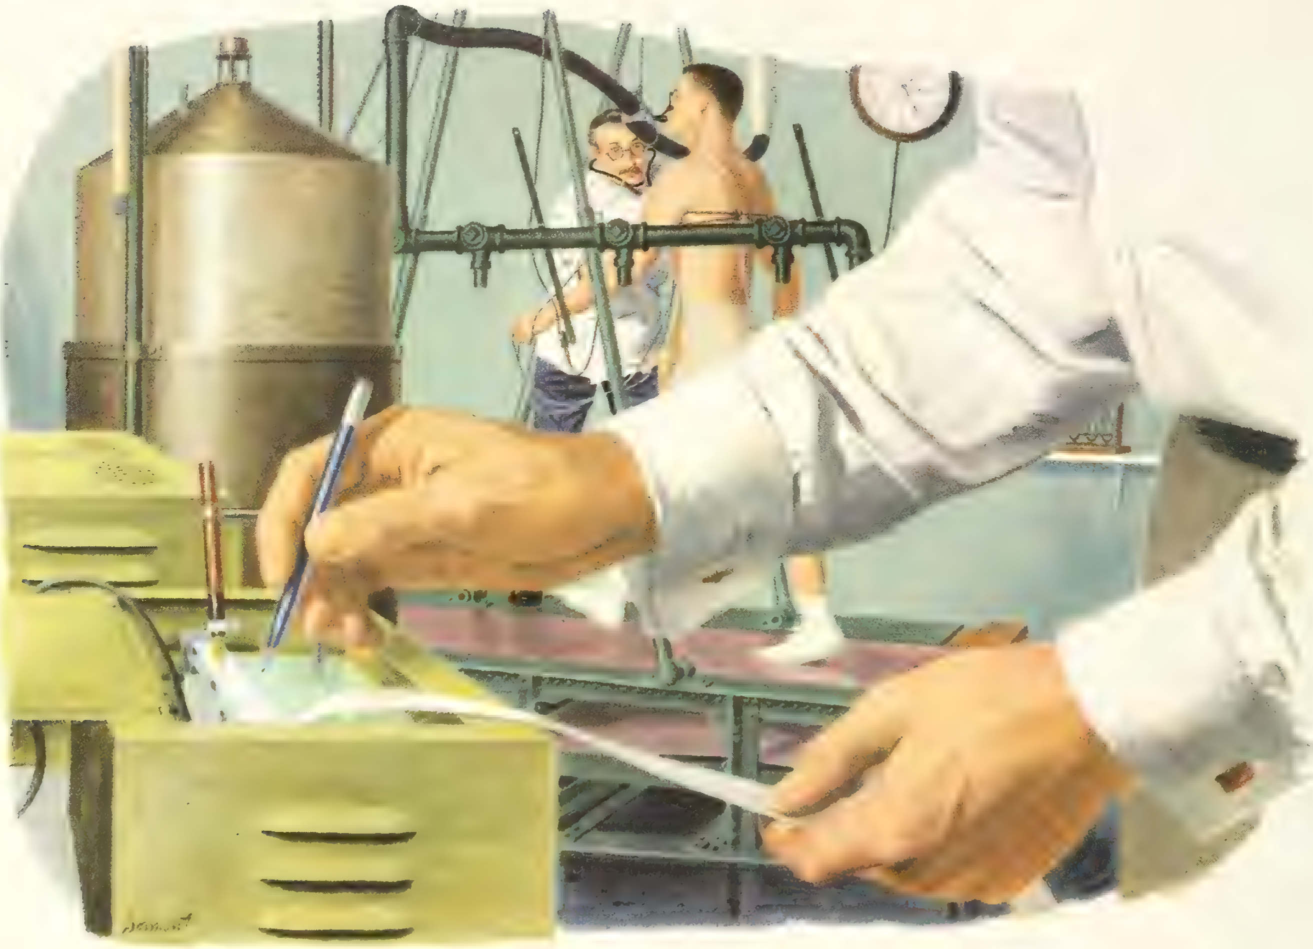
Lilly



'Amphedroxyn Hydrochloride' offsets fatigue
(METHAMPHETAMINE HYDROCHLORIDE, LILLY)

It has been demonstrated with human subjects that 'Amphedroxyn Hydrochloride,' by imparting a sense of increased energy, delays fatigue. This property enhances the usefulness of the drug which is used primarily to combat obesity by curbing the appetite. Although its potency permits it to be used at less frequent intervals than amphetamine, 'Amphedroxyn Hydrochloride' produces relatively few undesirable side-effects.

CORTISONE IN ALLERGIC MIGRAINE

J. S. BLUMENTHAL, M.D., F.A.C.P.

Minneapolis, Minnesota

WHILE allergic migraine is regarded as a disease entity characterized by periodic, usually unilateral headaches, associated with nausea, vomiting, various sensory and motor disturbances and a marked hereditary factor, it is also apparent that allergy may cause other types of headaches that do not have all these attributes. The diagnosis of migraine, however, must include at least some of the following:

> "1. Recurrent headache, usually throbbing and unilateral at onset, occurring against a background of relative well-being.
>
> "2. Temporary visual disorders preceding the headaches, such as scintillating scotomas, photophobia, hemianopsia and blurred vision.
>
> "3. Nausea, vomiting and irritability, occurring at the height of the attack.
>
> "4. Personality characteristics of inflexibility and shyness in childhood, giving rise to adult perfectionism, rigidity and resentment, ambitiousness and often efficiency.
>
> "5. A history of migraine in the immediate family.
>
> "6. Less frequent symptoms, such as parasthesias, speech disorders, dizziness, sweating and other vasomotor disorders.
>
> "7. Relief by ergotamine derivatives in about 85 per cent of the cases."[7]

The treatment of this condition has been a problem since its recognition. This is, of course, due to the frequently unknown cause of migraine. The present normally accepted theory of the mechanism is the vasomotor theory of imbalance involving spasm and dilatation. The exact cause of this imbalance and the factors responsible are, of course, the usually unknown and important ones. The very multiplicity of concepts—which include disorders of any and all of the endocrine glands, vitamin and dietary deficiencies, fluid imbalance, toxic agents, gastrointestinal and hepatic disorders, trauma, psychological factors—speaks for itself. While allergy as a major factor in the etiology of migraine has received increasing recognition, it is often impossible to detect the allergic agent and just as often impossible to eliminate it from the patient's environment. Successful treatment based on any and all of these theories frequently are reported. The most consistently symptomatically successful reports have come from the use of ergotamine derivatives. Prevention of an attack may often be best accomplished by psychotherapy and regulation of the life of the individual. There are, however, all too frequently patients who in spite of all efforts, all theories, all medications do not respond to any great degree. These patients have symptoms severe enough and frequent enough to constitute one of the most dramatic and serious of medical problems. It is these patients that require a new agent to alleviate their diffculties.

As allergic migraine certainly must also be regarded as primarily a disease of adaptation, Selye's[18] concept of the general adaptation syndrome is of great help in understanding this condition. Furthermore, as allergy is probably a major factor in a great many cases of migraine,[6] it may be theorized that the antigen stimulates the reticuloendothelial system, especially the plasma cells, to produce antibodies. The reaction of the allergen and the antibody results in toxic products which directly or indirectly stimulate

---

From the Section of Allergy, Department of Internal Medicine, University of Minnesota, Minneapolis.

the hypophysis to produce ACTH. Normally both mineralo-corticotrophic and gluco-corticotrophic stimuli affect the adrenals proportionately. If the response is too violent or the gluco-corticoids production is inadequate, allergic reactions result. As gluco-corticoids mitigate the response of shock organs to allergic stimuli and mineralo-corticoids increase the responsiveness, the degree of sensitivity would depend upon the balance between the two. How these gluco-corticoids diminish sensitivity in cells is not understood.

Immediately after the announcement that cortisone relieved the symptoms of rheumatoid arthritis, it was natural, as indicated by Selye's concept, to assume at once that all the so-called collagen diseases and hypersenstive states would be similarly affected, including migraine. White[24] has shown that animals that have had an adrenalectomy show extreme susceptibility to anaphylactic shock. Pretreatment of these animals with cortisone or ACTH gives them protection.[2] Rose and his associates[13] had demonstrated on rats the direct relationship between adrenal cortex and the metabolism of histamine and its specific enzyme, histaminase. The tissue and blood histamine was markedly increased and the mechanism for the destruction of histamine impaired following adrenalectomy.[14] They also demonstrated that the ability of histamine aerosols to produce dyspnea was blocked in four patients by ACTH therapy.[15,16] Segal[19] noted that the abnormal sensitivity of the asthmatic patient to injected histamine was lessened or abolished by treatment with ACTH on repeated injections; but Curry[3] noted no such protection against histamine or methacholine by single doses of 50 to 100 mg. of ACTH—an observation also made by Herschfus.[9] These studies would indicate that ACTH probably does not relieve bronchial allergic spasm through an antihistaminic or anticholinergic action. Cortisone and ACTH, as reported by Kendall,[10] are powerful tools with which it is possible to study problems related to the etiology and treatment of a large group of diseased. Though cortisone and ACTH can produce profound changes in the person with these conditions, the mechanism of action is still very imperfectly understood. It is certainly not a deficiency as no such deficiency of cortisone has been noted in asthma, or other conditions in which it is of such dramatic though temporary benefit. Sayers[17] suggests that cortisone acts by: (1) interference with the release of or toxic action of anaphylactic substances produced in antigen—antibody reactions; (2) alteration in cell permeability through its action on hyaluronidase; or (3) suppression of responses in mesenchymal tissues. It is easy to see that these types of action would definitely influence allergic manifestations.

When cortisone is given to rabbits, Rogan[11,12] noted a delay in the development of all elements of connective tissue response. This effect would, of course, interfere with the connective tissue reactions seen not only in hypersensitivity but also in disease activity and wound healing. Taubenhaus and Amromin[23] also noted an inhibition effect of cortisone on collagen formation and fibroblasts—the opposite effect from that of desoxycorticosterone.

White[24] believes that cortisone acts in the hypersensitive state by: (1) alteration in the relative concentration of antigen and antibody in the tissues; (2) alteration in the tissue factors which influence the combination; or (3) alteration in the tissue response to antigen-antibody reaction.

Be all this as it may, it is sufficient to state that there is early in the course of treatment with ACTH or cortisone physiological changes due to induced hyperactivity of the adrenal cortex. While the conditions treated with ACTH and cortisone have included almost all serious ones the body is heir to, some of the most dramatic results have been reported in the field of allergy with nearly 100 per cent encouraging though temporary results. As would be deduced from the effects of the hormone and confirmed by the literature,[21] absolute contraindications to the use of cortisone are few but it should be used with caution in diabetes mellitus, psychotic disorders, cardiac failure, during major surgery, severe infections, myocardial infarction, pulmonary embolus, cerebral accidents and probably because of its effect on connective tissue, in tuberculosis, syphilis and peptic ulcers. Equally important is the question of the effects of long continued administration and large dosage. As pointed out by Kendall and others, the answer is not a simple one. In general, however, the response is neither rapid nor long continued. The effects are reversible when the hormone is discontinued.

Beyond that, it is neither necessary nor desirable to give large doses for a prolonged period of time.[20] The immediate undesirable effects reported are fluid retention, moon face, acne, hirsuitism,[1] irregular menses, changes in mood or psyche, nervousness, fatigue, transient parasthesias, weakness, hypercoagulability, minor changes in carbohydrate metabolism and nitrogen balance.[21] These are usually not marked and are easily controlled by a reduction in dosage compatible with comfort. While the weakness noted at time has no constant relation to low serum potassium, it is at times desirable to give potassium chloride when the level is below normal. Low sodium diets will usually control fluid retention though very infrequently diuretics may be indicated. Estrone or progesterone will frequently prevent the most annoying of the symptomatic side effects in menopausal women. Above all, suboptimal dosage will minimize these undesirable features as well as the danger of poor healing, missing new clinical symptoms such as active infections, pain, fever, peritoneal irritation from perforated ulcers[4,5,8] as well as the changes of hypperadrenocorticism.[22]

Because of these reports, and as cortisone became more available and relatively less expensive, it was used when the opportunity presented itself to give this hormone to a patient, with migraine probably allergic, who had failed to respond to all types of medication, was desperate, was a definite allergic individual, could afford the treatment, for a prolonged period of time if necessary, and in whom there were no apparent contraindications.

Case Report

E. W., a thirty-six-year-old, white, married executive came to see me February 28, 1950, with complaints of right-sided headache for the past ten years but markedly worse the last five months; dizzy spells of the same duration; hives all his life; asthma ten years and a stuffy nose with a copious watery discharge all his life. The headache was accompanied by nausea and vomiting and usually started with a peculiar odor in his nose, swelling of his eyes and increased plugging of his nose. The attacks had been about the same—once a month up to five months ago and moderate in severity, lasting from a few moments to several hours. Since then they have increased in duration, severity and frequency until now they are more or less constant. Suicide has been seriously and frequently considered. Alcohol was the only known aggravating factor. His asthma, hives and stuffy nose have remained the same through the years, though these are aggravated by dust, chocolate, lemons. There is no seasonal variation or environmentl factors that have been noted by this very intelligent individual. The migraine is so much the overwhelming symptom that all else is secondary. The only symptomatic relief has been given by cafergot (1 mg. of ergotamine tartrate and 100 mg. of caffeine alkoloid) if taken very early in an attack—with relief only at times and only moderate—and in dosage of up to eight tablets at a time and frequently. He had used this dangerous amount in desperation and with full knowledge of the risks involved. Treatment by many capable internists, psychiatrists and allergists with diets, desensitization, climatic changes, hospitalization, fever therapy, innumerable antihistamines, antibariums, parasympathetic depressants and sympathetic stimulants, and nonspecific drugs have been of no avail. He was truly desperate. His past history was essentially negative. The family history showed that his mother had migraine headaches and hives which decreased in intensity with age. One sister, aged forty, and one brother, aged twenty-six, have migraine headaches of moderate severity but no other allergic manifestations.

Physical examination is essentially negative but for the boggy allergic rhinitis type of mucous membrane, and a few expiratory wheezes in the lungs. Routine laboratory work was negative but for a 4 per cent eosenophile count in the peripheral blood. Chest plate, electrocardiogram, basal, skull pates were normal. Skin tests, intradermally, showed very many positive reactions but did not correlate with the history.

Because the patient was really in great distress and very depressed, histamine was given intravenously daily for eighteen days with moderate relief of headaches. Histamine, subcutaneously, was then given daily. At this time the patient was started on an elimination of contact and inhalants which were positive on skin tests. While the allergic rhinitis improved on this regime, the asthma was the same—almost nightly attacks. On elimination diets this also improved. The patient continued on this regime with daily injections of histamine given by the patient himself until October 10, 1950. During this period, however, though his headaches remained less severe, he still had to take 2 tablets of cafergot once or twice a day. Beyond that, he was very lethargic. He said he could not do his work if he took histamine because of lack of energy, and because of his headaches if he did not take histamine. Graduations in dosage were tried as was desentization with dust and testosterone but to no avail.

On October 10, 1950, he was started on 200 mg. of cortisone daily for two days—with all other medication stopped—then 100 mg. daily for one week and the dosage gradually reduced until October 26 when the hormone was discontinued. After the first dosage he felt much better, and had no headaches, felt elated as is usual with cortisone but still had some wheezing and rhinitis. His urine, weight, and blood pressure remained normal during treatment. He had few headaches until November 17, 1950, when he started to become progressively worse and returned to his pretreatment level. On December 7, 1950, he returned to see me, at which time cortisone was again started with a similar response to the first series. On December 16 he was placed on a daily maintenance dose of 50 mg. of cortisone orally (25 mg. a.m. and p.m.). He tried several times to stop or reduce the drug but noted recurrence of symptoms within a few days to such an extent that renewal was urgent. He has been symptom free except for occasional wheezing of mild degree. He is at full time work and the only complaint he has is as to the expense of therapy. No complications have arisen and there has been no change in physical or laboratory findings.

While cortisone is certainly not the treatment of choice in allergic migraine, his condition, complicated by asthma and rhinitis, which had resisted all other types of therapy and in which the situation was truly desperate, did respond to this hormone. I will attempt at intervals to stop treatment and/or reduce dosage. Up to the present, under continuous control, no complications have arisen with a dosage of 50 mg. of cortisone daily. It is to be hoped that time and aging will, as usual, take care of the probable basic cause of his migraine: the ability of his cranial vessels to become initially constricted with later hypotonicity.

REVIEWS OF MEDICAL MOTION PICTURES

The Committee on Medical Motion Pictures has completed the 1951 supplement to the second revised edition of the booklet entitled "Reviews of Medical Motion Pictures." This supplement contains 90 reviews of medical and health films reviewed in *The Journal of the A.M.A.* from January 1, 1951, through December 31, 1951. Each film has been indexed according to subject matter. The purpose of these reviews is to provide a brief description and an evaluation of motion pictures which are available to the medical profession.

Copies have been sent to the secretary of each of the State Medical Societies. Complimentary copies will be sent to County Medical Societies and other medical organizations upon request from: Committee on Medical Motion Pictures, American Medical Association, 535 North Dearborn Street, Chicago, Illinois.

HISTOPLASMOSIS

MILDRED CARIKER, M.D., M.S.

Rochester, Minnesota

IN 1905, S. T. Darling was the pathologist at Ancon (now Gorgas) Hospital, Canal Zone, Isthmus of Panama. In December of that year, on making histologic examinations of material taken at necropsy of a Negro from Martinique, who had died at the age of twenty-seven years, Darling[2] made an important finding. In the lungs, spleen and liver were tubercles which grossly resembled those of tuberculosis. On microscopic examination, however, in large mononuclear cells lying in the pulmonary alveoli and free in the plasma of the spleen and bone marrow, were multiple round to oval bodies, 1 to 4 microns in diameter, with refractile rims. In 1908 Darling[3] reported in detail three cases in which these bodies were found generally in lungs, bone marrow, spleen and liver, and in ulcerations of the small and large intestine. He compared his findings with those of Wright, Leishman and Donovan, reported in 1903, and concluded that the organisms that he had found were not the same as those which they had described and which became known as Leishman-Donovan bodies.

Darling's recorded clinical findings were meager, for the patients had been admitted in terminal stages of the disease, but constant fever, emaciation, enlarged spleen and liver, cough, vomiting, diarrhea, anemia and leukopenia were noted. Darling considered the disease to be a general protozoan infection and suggested that the organism be named "Histoplasma capsulatum" and the disease, "histoplasmosis."

Following the writings of Darling there were no more reports of this disease until, in 1926, a case originating in Minnesota was announced by Riley and Watson.[11] By 1934, ten cases had been reported, all ending fatally.

In that year, 1934, DeMonbreun[4] recovered the causative organism in the first case in which diagnosis was made while the patient was alive. A baby, six months of age, was admitted to the hospital with fever, anemia, cough, enlarged spleen, enlarged liver, and roentgenologic findings characteristic of severe bronchitis. The diagnosis was made by finding the yeast-like organisms in films of peripheral blood. The patient died twelve days after admission to the hospital. At necropsy, tissue from the spleen was obtained and was used for inoculation of several types of media; a fungus was grown which assumed both mycelial and yeast-like forms. The latter grew on media high in protein, and DeMonbreun concluded that the yeast-like form was the parasitic and pathogenic form. This fungus, given intravenously to monkeys, produced a disease like that seen in the child, both from clinical and pathologic standpoints, and the yeast-like and mycelial forms were recovered from the test animals.

The fungus has been classified as one of the moniliaceae of the Fungi imperfecti. The mycelial form has branching, septate hyphae with terminal tuberculate conidia and can be grown on any media favorable to fungi. The yeast-like form, which is thin-walled and oval, and reproduces from a single bud at one end, can be found on passing the fungus through animals or by growing the fungus on a medium high in protein. DeMonbreun postulated that it might occur as a sprophytic fungus free in nature.

As the disease became better understood, more cases were reported, until 123 had been described in the literature by 1949. No doubt the correct diagnosis has been made in a number of cases which have not been reported. The disease is recognized as a systemic one. At first it was thought to be invariably fatal, but in recent years an increasing number of reports have been made of a possible subclinical form, characterized by pulmonary calcification and a positive skin test.

The disease has been encountered in most of the countries of the world but at least three fourths of the cases have been reported from the United States. This latter fact is considered to be attributable more to the interest which the condition has aroused in the United States than to high comparative prevalence here. Patients have come from twenty-five states and, of these, a predominant number have resided in states situated in the middle of the Mississippi Valley and west of the Appalachian foothills.

Patients ranging in age from two months to seventy-seven years have been attacked, and patients in at least a sixth of reported cases have been in the first year of life. The disease occurs twice as frequently among males as among females.

In the presence of active, acute infections the clinical symptoms may refer the examiner to one or more bodily systems, or they may be generalized, as the disease is essentially a systemic one. There is irregular fever, loss of weight even to such degree that the patient is emaciated, has marked weakness and diaphoresis. Any portion of the skin or mucous membrane may present ulceration, granulomatous swelling and papules. Such lesions, if they are on the lips, tongue, tonsils, palate or pharynx, are very tender and often make it difficult for the patient to eat. The cervical as well as the inguinal lymph nodes may become tender. Respiratory symptoms may be prominent. Among 123 cases of histoplasmosis collected by Hodgson, Weed and Clagett[7] were found sixty-two in which they considered pulmonary histoplasmosis to be proved. A persistent cough, with or without expectoration, is a dominant symptom. Dyspnea and pleural pain also are present and, less frequently, hemoptysis. The gastrointestinal manifestations of anorexia, nausea and vomiting may accompany the disease when it affects organs other than those of the gastrointestinal tract but, when the gastrointestinal tract becomes ulcerated, abdominal distention, diarrhea and melena are added. In terminal stages there may be neurologic symptoms, including signs of meningitis.

The physical findings are variable. They may be predominantly referable to one organ, but more often the lesions are multiple, and the signs, therefore, are often referable to more than one organ. Usually, there is some pallor and evidence of loss of weight. The skin lesions take the forms of subcutaneous nodules, abscesses, ulcerations and purpuric spots and may appear anywhere on the skin. The mucous membranes are very vulnerable. Weed and Parkhill[13] reviewed seventy-three cases and found that, in twenty-four, oral lesions were present; moreover, they added four cases in which the presenting lesions were of the mouth and pharynx. These lesions were deep, sharp-edged ulcers of the tongue and granulomatous plaques of the floor of the mouth, tongue, palate and pharynx.

On roentgenograms, evidence of pulmonary involvement is in no definite pattern and in only about a third of the cases the formation is found which usually is attributed to a fungus infection; that is, peribronchial infiltration extending radially from the hilus. In the remaining cases the lesions may appear as localized infiltration, pneumonic consolidation, generalized miliary involvement, or as definite nodules. Cavitation is of infrequent occurrence but has been found; more frequently there is calcification. Hilar nodal involvement and mediastinal widening are evident in cases wherein lymphadenopathy is prominent.

The liver and spleen were enlarged in Darling's cases, and such enlargement has been described in more than half of the cases reported since. Ulcerations at the anal margin tend to be sites of hemorrhage, as do similar ulcers in the sigmoid. Hypertrophy of superficial lymph nodes or of all lymph nodes frequently is prominent. The cervical nodes are especially affected and are easily accessible for biopsy.

Less common physical evidences of the disease have been cited by Parsons and Zarafonetis[10] in their review of seventy-one cases and report of seven. Involvement of the middle ear and aural canal occurred in eight of the seventy-one cases, and true otitis media in five of the eight; in one case there was massive involvement of the nasal septum. A mitral lesion was diagnosed in life and, at necropsy, vegetative masses were found on the valve; these vegetative masses contained the causative organism. Evidence of moderate to severe anemia and leukopenia frequently is found on laboratory examination.

Since DeMonbreun[4] in 1934 gave proof of the etiologic agent, the diagnosis of histoplasmosis is being made with increasing frequency while the patient is alive. Cultures are highly reliable. Culture of sputum, of material obtained by gastric lavage, of pleural fluid, and of bronchial secretions obtained by bronchoscopy should lead to correct diagnosis of pulmonary histoplasmosis. Culture of material obtained at surgical operation or at biopsy often is the means of making a diagnosis; this is a valuable adjunct to histologic examination. Weed and Parkhill[13] have advised using the emulsified tissue for inoculation of blood agar plates; the medium contains 50 units each of penicillin and streptomycin to 1 cc. to inhibit bacterial growth.

Direct smear from an ulcerated surface may give the diagnosis; however, only in ulcers of recent development is the fungus usually demonstrable histologically.

The histologic picture at biopsy is a composite of necrosis, exudation and proliferation. The necrotic tissue only occasionally undergoes liquefaction. The exudate is made up of polymorphonuclear leukocytes and lymphocytes and the proliferation is composed of fibroblasts and macrophages. It is in this last type of cell that the round to oval, basophilic staining, causative fungus, Histoplasma capsulatum, with its refractile rim, is found, usually packing the cytoplasm with its members.

Sternal puncture has been responsible for several positive diagnoses, the material being subjected to the same procedures as biopsy material which, in fact, it is. Also, a smear may be made of this material, but a smear is less likely to give positive findings. Culture of peripheral blood has given positive results usually in the last days of a fulminating case of the disease, or at the height of an acute febrile episode.

The skin test is having more general use, and is of special value in epidemiologic investigation of pulmonary lesions. Its accuracy has been under discussion in that it has been found to give cross reactions when applied to persons sensitized to other fungus infections, especially in instances of blastomycosis and coccidioidomycosis; even the common Candida albicans has been suspected of entering into the reactions. Smith and associates[12] found an increasing number of nonspecific cross reactions to coccidioidin as the sensitivity to histoplasmin rose; however, they did not think the cross reactions interfered with the interpretation. They also found that if the reactor was dominantly sensitive to coccidioidin, there was a much higher degree of cross reaction to the histoplasmin test than otherwise, and in addition, those who were in the process of coming down with the disease, coccidioidomycosis, and were positive to coccidioidin, gave cross reactions with both histoplasmin and blastomycin.

Iams[8] has made a study of all the reports of skin tests made with histoplasmin, a total of 27,780 tests. Of these, in 38.6 per cent the result was histoplasmin positive. In 18,746 instances, both the histoplasmin and the tuberculin tests were done, with the following results: histoplasmin positive, 44.13 per cent; tuberculin positive, 8.41 per cent and, finally, both histoplasmin positive and tuberculin positive, 4.05 per cent. In an even further classification, histoplasmin and tuberculin tests were done on 2,577 persons whose pulmonary roentgenograms gave evidence of calcification; of these, 82.5 per cent were histoplasmin positive and 18.3 per cent were tuberculin positive. Iams has expressed the belief that the variables that may influence the test are the lot and dose of the antigen, and the sensitivity of the receiver to one or more mycotic antigens.

The complement-fixation and precipitin reactions have been brought into use in the last few years. They are still not entirely reliable because of cross reactions with the antigens of other fungi. Kunstadter, Whitcomb and Milzer,[9] however, reported them to be useful in distinguishing between latent and active histoplasmosis in that the titer reaches the peak in the acute phase.

At necropsy, all tissues of the body have been found to be involved. The most involved organs, in order of frequency of involvement, are the lymph nodes (localized and generalized involvement), liver, lungs, spleen, suprarenal glands, intestinal tract, bone marrow, kidneys and oropharynx. The suprarenal glands may be found to be entirely destroyed by necrosis, and the illness, in such a case, may have been diagnosed as Addison's disease. Grossly, the lesions of the lungs suggest the tubercles of tuberculosis, and it remains for histologic examination to furnish the diagnosis. The general picture is one of necrosis and formation of granulomatous tissue, with or without ulcerations of mucous membranes. The disease has been diagnosed incidentally at necropsy when death was from another cause. Christie[1] reported six such cases. Four of the six patients were infants less than one year of age; Histoplasma capsulatum was cultured from tubercles in the lung and from cervical and mediastinal lymph nodes.

Clinically and histologically, the disease has been confused with toxoplasmosis, cryptococcosis and leishmaniasis, and clinically it often is mistaken for one of the granulomatous diseases, such as syphilis or tuberculosis. Addison's disease, leukemia and blood dyscrasia also have been offered as clinical diagnoses. Histologic diagnoses have included lymphoblastoma, Hodgkin's disease and carcinoma.

In treatment of the disease many substances have been tried but none has proved satisfactory. Various compounds of potassium, antimony, bismuth and arsenic have been used. Radiation has been employed in a few instances for relief of pain from swelling of lesions in the oropharynx. Parsons and Zarafonetis[10] wrote of a lesion of the tongue which first was diagnosed as an epithelioma, grade 1, and which was subjected to radiation but when this lesion recurred it was found to be positive for Histoplasma capsulatum and again was subjected to radiation. Five years later the patient was well. A boy, twelve years of age, who had an infection of the upper part of the respiratory tract, and high fever, and whose thoracic roentgenogram gave evidence of infiltraton of the lung, was treated by Kunstadter, Whitcomb and Milzer[9] with penicillin and salicylates. Early animal inoculations of bronchial secretions and cultures of peripheral blood were positive for Histoplasma capsulatum. Four months later the lung was healed by calcification. Patients have been known to be alive from one to sixteen years after diagnosis; those who lived longest usually had lesions of the skin.

Two cases have been reported by Hodgson, Weed and Clagett[7] in each of which lobectomy was performed for a single pulmonary lesion. One patient was a man, thirty-six years of age, whose symptoms were hemoptysis and abundant sputum. The thoracic roentgenogram gave evidence of a cystic lesion of the lower lobe of the right lung. A culture of sputum yielded Histoplasma capsulatum. The pathologist who examined the surgical specimen reported finding a gray-white mass with a partially necrotic center. This mass consisted of granulomatous tissue composed of necrotic material and fibroblasts which contained Histoplasma capsulatum. Here, the fungus seemed to be invasive rather than to have been phagocytosed by the tissue cells. There was infiltration with lymphocytes, plasma cells and phagocytes containing Histoplasma capsulatum. Two years later physical examination gave a negative result. The other patient was a woman, thirty-five years of age, who had a lesion of the upper lobe of the right lung and whose sputum, when cultured, was positive for Histoplasma capsulatum. The fungus also was grown from the surgical specimen. The woman was well four months later. The authors believed that in rare instances surgical operation on the lung might be advisable if a localized lesion was found even though the disease is usually systemic, for they considered that surgical removal might delay a more serious outcome. It must not be forgotten that the nature of the disease is to become disseminated and rarely is there enough localization to permit surgical treatment. Histoplasmosis may be present for years without serious lesions developing and yet finally, when a latent focus becomes activated, the disease may prove fatal.

In the last fifteen years, among asymptomatic persons found in epidemiologic surveys, there has been increasing interest in the occurrence of pulmonary calcification in the presence of negative tuberculin tests. Pulmonary calcification always has been considered to be indicative of a healed lesion of tuberculosis, and an accompanying positive result of the tuberculin test would be expected. But the same roentgenologic picture, accompanied by a negative tuberculin test, was appearing increasingly in the states bordering the Mississippi River basin and the western slopes of the Appalachian Mountains. It was in these areas that a majority of the reported fatal cases of histoplasmosis had occurred. The antigen for making skin tests for histoplasmosis became available and, in a high percentage of these puzzling cases, the reaction was positive. Some doubt has been expressed concerning the accuracy of the response as cross reactions are known to be possible. But with improvement of the antigen and standardization of the laboratory procedure cross reactions are becoming less possible; moreover, Histoplasma capsulatum has been recovered in some of these asymptomatic cases.

The significance of the asymptomatic pulmonary form of histoplasmosis is that in some points it resembles pulmonary tuberculosis so closely as to be confused with it. In both conditions the antecedent lesions are soft and infiltrative and, in both, pulmonary calcification is a feature. The presumptive diagnosis rests on the patient's sensitivity to tuberculin or histoplasmin and, possibly, on recovery of the causative organism. Healing by calcification can occur in the presence of either disease. For instance, in a case reported by Kunstadter, Whitcomb and Milzer,[9] and mentioned earlier in this paper, events began with a nonproductive cough and fever. The thoracic roentgenogram was negative coincident with a positive histoplasmin test. Progress thereafter was through a febrile course accompanied by pulmonary infiltration, and during these developments Histoplasma capsulatum was cultured from the blood and from lesions induced in animals inoculated with bronchial secretions. Finally, resolution and calcification occurred. The entire course just described occupied five months.

A careful study of the relationship between pulmonary calcification and sensitivity to histoplasmin has been made by Furcolow[5]; his subjects were Kansas City school children. For two years he followed the progress of several hundred children whose roentgenograms gave evidence of pulmonary infiltration; results of their tuberculin tests were negative, and of their histoplasmin tests, positive. From the lungs of some the infiltrate disappeared and in those of others it became fibrotic, but in most of the cases calcification was the manner of healing. Furcolow reported individually seventeen such cases. In the precalcific roentgenograms there was evidence of disseminated or localized pneumonic infiltration or nodular foci. Cultures of peripheral blood, of pharyngeal secretions, of bronchial secretions and of material obtained on gastric lavage were made. One gastric culture was positive for Histoplasma capsulatum and one culture from the tonsil was positive. Calcification occurred in all lesions and hilar nodes as evidenced by thoracic roentgenograms.

In August, 1950, Furcolow[6] reported sixteen cases, in all of which the patients were acutely ill with the disease. Dominant symptoms and findings were referable to the lungs. In each case Histoplasma capsulatum was cultured from sputum, from material obtained by gastric lavage, from sternal marrow, from surgically removed tissue or from peripheral blood. Of these patients, five recovered from the acute phase, and calcification was the terminal finding at the site of the lesion. In one case there was no residual sign of the disease. At the time of the report, all of the patients were well.

Summary

As diagnostic methods improve, the systemic disease, histoplasmosis, is becoming increasingly important, for it is of more frequent occurrence that has been realized. Since Darling carefully and accurately described the findings at necropsy and the causative organism of the disease as early as 1906, it has become known not only as a fatal disease but as one having also a subclinical form and leaving residual signs such as pulmonary calcification. This makes necessary consideration of histoplasmosis in the differential diagnosis of any lesion of the lung, of any ulceration of the skin or a mucous membrane, of any granulomatous lesion or of any lymphadenopathy. Methods of culture of the etiologic agent, Histoplasma capsulatum, are now well known. The fungus has been grown from material obtained at biopsy or at surgical operation, from sternal marrow, from material obtained by bronchial or gastric lavage, from peripheral blood and from secretions taken directly from ulcerated surfaces.

Since it is a disseminated disease, symptoms may be referable to one or all systems of the body. Pulmonary and oropharyngeal manifestations are of frequent occurrence, as are gastrointestinal symptoms; with any of these, weakness, loss of weight and fever are common findings. At necropsy the organism has been found in every organ but particularly in the lungs, liver, spleen, lymph nodes, suprarenal glands, bone marrow, intestinal tract and oropharynx.

No specific medication has been effective. Isolated patients have been treated with penicillin during a febrile course and have survived, but if antibiotics have been used widely, the fact has not been reported. If the disease is limited apparently to one region, such as a lobe of a lung, surgical removal has been effected with subsequent return of health. But it must be remembered that the disease tends to become disseminated and that it may reappear in the same or a distant organ.

The asymptomatic form of the disease is important, not only for itself but because of the necessity of distinguishing it from pulmonary tuberculosis, as healing by calcification may take place in both. A negative tuberculin test in the presence of a positive histoplasmin skin test has been a factor in deciding for the tentative diagnosis of histoplasmosis and, with the intensification of diagnostic efforts, the causative agent,

TRAUMATIC AMPUTATIONS THROUGH THE FOOT

HARRY B. NEEL, M.D.
Albert Lea, Minnesota

IN an agricultural and industrial community the general surgeon must devote a considerable part of his time to the treatment of trauma. Every effort is exerted to save life, to preserve function and to shorten the period of disability. These objects have always been important to both patient and surgeon, and now, with the increasing legal responsibilities of the employer, the haste with which the injured seeks settlement in court, and the liberal awards granted by some judicial bodies, a third party—the employer, or an insurance company, or another party to an accident—has become greatly interested in attaining these objectives.

Injuries on the highways are certainly increasing with great rapidity, and farm accidents seem far too frequent in agricultural sections. It is my impression that safety precautions instituted by railroads and by industry have effected a diminution in the number of injuries sustained by railroad and industrial workers.

The hand is frequently the site of injury in farm and factory accidents. The machines most commonly responsible for these injuries are cornpickers, saws, punch presses, shredders and belts on machines and motors, to mention a few. In our experience injuries to the foot are far less common and are caused by falling objects, axes, by the feet of farm animals, and by firearms. In the two cases to be presented the foot was partially amputated by the wheels of a train.

When a severely injured individual is seen in the emergency room, the extent of his injuries should be rapidly determined and his general condition evaluated. To me it has seemed wisest to defer thorough exploration of the large wound until anesthesia has been obtained. If shock is a complicating factor, whole blood transfusion and intravenous fluids are indicated and should be readily available. In many instances it is advisable to evacuate the stomach before the administration of general anesthesia.

In the operating room I like to have a large needle in a vein. Intravenous fluids may be given slowly and if blood has not already been started, it can be easily given, should the necessity arise. The anesthetic which we prefer is intravenous sodium pentothal, supplemented with oxygen by mask, and with nitrous oxide if necessary. During the war it was demonstrated to my satisfaction that these agents constitute the best anesthetic for emergency treatment of wounds of the extremities.

Wounds of the foot may contain ground-in dirt, cloth, leather and grease. The adjacent skin may be crushed. It is our practice to shave the skin, to clean the wound and adjacent skin with soap and water, removing all foreign material during the process. The wound is then irrigated with copious quantities of sterile water. Finally, the skin is dried and painted with tincture of iodine, and sterile drapes are applied.

We now turn to the most important step in the prevention of infection, especially gas gangrene, and that is debridement of the wound. All crushed and devitalized muscle must be excised, dangling ligaments, fragments of tendons and loose fragments of bone removed, bleeding points clamped and ligated, and nerves cleanly cut off so their ends will retract into healthy tissue. It is desirable to preserve bone length but at the same time to avoid leaving those parts which later will become an impediment to good function.

It is difficult to determine the level of skin viability. We have reasoned that it is better to be conservative in removal of skin and to use the available skin to loosely close the wound. At a later date it may be necessary to trim away skin which becomes necrotic and to devise other methods for final wound closure.

The great toe, the most important of the toes, is useful in maintaining a smooth gait and is the only single toe to be left on a foot. All possible length of the great toe should be preserved if it is involved in an injury. A remaining single minor toe serves no useful purpose and because of progressive deformity, it may become the source of annoyance.

A foot stump must have good skin coverage, and muscle balance must be maintained. There is some controversy about the advisability of using skin grafts to cover wounds of the foot. In some instances skin grafting has permitted a longer stump and has accelerated wound healing. The graft assumes some of the characteristics of the normal skin of the recipient area and ulceration becomes a smaller problem as time goes on.

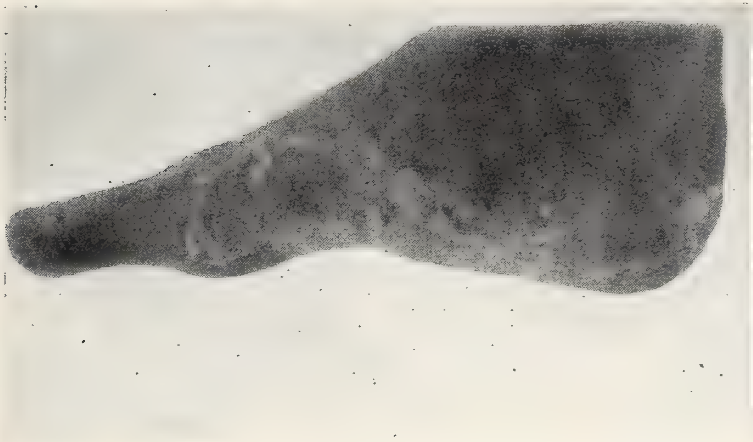

Fig. 1. Foot of boy, aged seven years, following amputation of four small toes, and skin grafting. Good functional result.

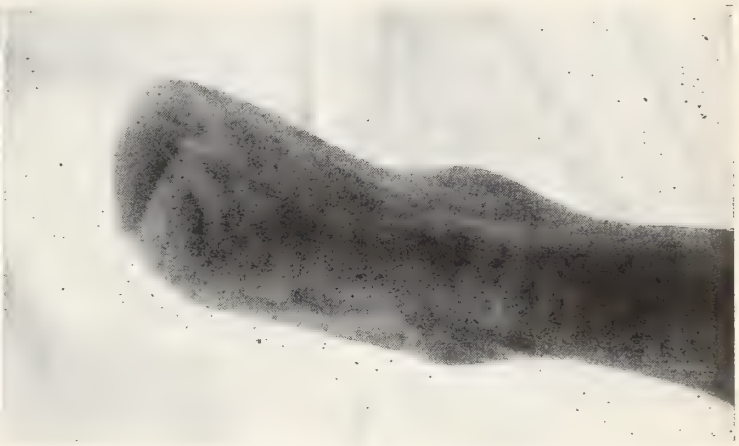

Fig. 2. Foot of a brakeman following amputation of the toes by the wheel of a freight car.

The following cases, both railroad accidents, illustrate some of the points under discussion. In each instance the final result has been gratifying.

Case Reports

Case 1.—On the afternoon of July 28, 1950, a little boy, seven years of age, was running beside a moving freight train. He "stubbed his toe," fell, and his right foot was crushed by the wheel of a car. Unknown persons brought the little patient to the hospital at once.

Examination in the emergency room disclosed a slender but well-developed boy of seven years. He was a trifle pale. The pulse was rapid. The heart and lungs were normal to percussion and auscultation. There was no evidence of injury other than to the right foot, the lateral part of which was crushed, and the four minor toes were dangling. Bleeding was moderate.

In the operating room intravenous fluids and whole blood were administered intravenously. The patient was anesthetized with vinethene and ether. The right foot and leg were cleaned with soap and water and the wound irrigated with large quantities of sterile water. The skin was painted with tincture of iodine. It was necessary to remove the four minor toes and their metatarsal bones, all of which were fractured and fragmented. The third cuneiform and the cuboid bones were also crushed and bone fragments were removed. Devitalized muscle was trimmed away. Bleeding was carefully controlled by ligatures of fine catgut. Flaps of skin of questionable viability were used to cover the wound. Dressings were applied. A prophylactic dose of gas gangrene-tetanus antitoxin was given and penicillin was given intramuscularly.

On August 5, August 11 and again on August 16 the dressings were changed under rectal pentothal anesthesia. The skin flaps did not survive, so non-viable skin was trimmed away at the line of demarcation. The great toe was in good condition and completely covered with skin. A healthy appearing granulating surface, extending from the heel to the base of the great toe, was approximately 6 inches in length and 3 inches in width.

Wet dressings of normal saline were applied for a few days. On August 26, under rectal pentothal, vinethene and ether anesthesia, a split skin graft 12/1000 of an inch in thickness was taken from the abdomen with the dermatome. This graft was applied to the granulating surface on the right foot and secured with sutures of fine cotton. Pressure dressings and a plaster cast were applied.

The cast and dressings were removed on September 7. The graft was found to have taken very satisfactorily. The edges of the wound soon healed. At first the patient was reluctant to put his foot to the floor but he rapidly resumed his normal gait, wore Western shoes and had no limp.

Case 2.—A brakeman, forty-one years of age, was brought to the Naeve Hospital at 12:45 a.m. on February 11, 1951. The ground was covered with snow and ice, and the patient stated that while looking for a hot box he slipped and the wheel of the train crushed his left foot. He hobbled to a nearby store where assistance was obtained and arrangements made to transport him to the hospital.

The patient was pale but in good general condition. His complaints were restricted to the left foot which was encased in bloody cloths. Examination revealed that the toes of the foot were dangling by their skin attachments. The phalanges and distal ends of all metatarsal bones were fractured and exposed. After a hypodermic injection of morphine sulphate and atropine sulphate the patient was taken to the operating room.

In the operating room intravenous fluids were started, and the patient was anesthetized with pentothal sodium and oxygen. The wound and adjacent skin were thoroughly cleaned with soap and water followed by irrigation with copious quantities of sterile water. The dangling toes were removed, the wound was debrided of devitalized muscle and tendons, and the ends of the metatarsal bones were rongeured with preservation of all possible length. There was a long flap of skin from the planter surface of the foot which was brought up and sutured loosely to the skin on the dorsum of the foot. A small drain was brought out through one corner of the wound, a pressure dressing was applied, and the patient returned to his room in good condition.

A prophylactic dose of gas-gangrene-tetanus antitoxin was given and penicillin therapy started. There was never any evidence of infection, but it soon became apparent that all of the skin flap would not survive. When a line of demarcation developed, the gangrenous tissue was excised and wet dressings applied. A healthy granulating surface soon developed.

On March 10, 1951, under pentothal sodium and cyclopropane anesthesia a split skin graft was taken from the left thigh with the dermatome. The graft was placed on the granulating surface of the left foot and secured with sutures of fine cotton. A pressure dressing was applied.

The dressings were changed for the first time on March 20. The graft had taken satisfactorily and the wound edges healed in fairly rapidly. The patient was dismissed from the hospital on March 28 and was seen as an out-patient thereafter. A prosthesis, consisting of a metal inner-sole for the full length of the shoe and with a pad at the distal end, was secured. The patient walks with a slight limp.

HISTOPLASMOSIS

(Continued from Page 217)

Histoplasma capsulatum, has been recovered from asymptomatic individuals.

The fungus has been thought to be free in nature. Possibly it causes disease by effecting contact with mucous surfaces other than those of a lung, or by material containing the fungus being inhaled. The finding of gastrointestinal lesions has led to consideration of the mouth as a portal of entry. The disease has been found in most countries. Particular interest in diagnosis is evident in the United States, and here the diagnosis most often has been made in the states of the Mississippi River basin and of the western slopes of the Appalachian Mountains.

THE HYPERSPLENIC STATE

Report of Two Cases Treated by Splenectomy

F. W. CONLEY, M.D.
Duluth, Minnesota

HYPERSPLENISM, through the years, has been the subject of much controversy. Morawitz and Eppinger, in 1919, suggested the use of the term to designate a hyperactivity of the spleen with resultant blood cell depletion.[3] That the spleen may become functionally overactive has been proven by Wiseman and Doan,[18] who described primary splenic neutropenia, reporting five cases, some of which, in addition to the neutropenia, showed a hemolytic anemia and a thrombopenia. They stated that anatomically the spleen consists of three structures: (1) the reticulo-endothelial system, (2) the lymphatic component, and (3) the vascular spaces. They were of the opinion that the diseased state is due to hypersplenism in which the reticulo-endothelial cells of the spleen destroy leukocytes at an accelerated speed. It is generally agreed that the spleen has three major functions[2]: (1) the destruction of red cells, (2) the storage of blood, and (3) the production of lymphocytes from the lymphoid elements of the organ.

How the condition seen in hypersplenism causes the cytopenias has been the subject of debate. The European workers[4,9] have theorized that there is a hormonal relationship between the spleen and bone marrow. They feel that the reticulo-endothelial cells of the spleen produce a hormone which suppresses maturation of blood cells in the marrow. This theory is also supported by Singer et al.[13] However, most American hematologists, on the other hand, favor the phagocytic hypothesis, in which the cell depletion is thought to be due to increased phagocytic activities of the enlarged spleen. In support of this, Wiseman and Doan have shown, through direct supravital studies of the splenic parenchyma, that increased phagocytosis exists. This is further upheld by the report of Hirschboeck[8] who studied a case of Felty's syndrome in which he obtained blood from the splenic vein, prior to splenectomy, which showed 2,600 white cells, and from the splenic artery which showed 11,700 white cells.

The clinical syndromes that have been described under the heading of hypersplenism by Kracke[10] include (1) chronic splenic neutropenia, (2) acute splenic neutropenia, (3) acute and chronic splenic panhematopenia of both congenital and acquired types, (4) familial hemolytic icterus, and (5) idiopathic thrombopenic purpura. Kracke also feels that the depleted cell values of so-called aplastic or hypoplastic anemia may be intensified by increased or normal activity of the spleen and that certain other diseases, such as Hodgkin's, Felty's, et cetera, which involve the spleen, may also be accompanied by an increased splenic cellular destruction. The diagnostic criteria for hypersplenism as suggested by Kracke include (1) a spleen that is clinically enlarged, the single exception being found in some cases of essential thrombopenic purpura; (2) depleted cell values in the blood including neutropenia, thrombopenia, or anemia, or various combinations of these; (3) the demonstration of the fact that bone marrow production is not impaired; and (4) the demonstration of splenic overactivity by the use of the epinephrine test. Dameshek and Estren, on the other hand, feel that the epinephrine test does not show conclusive results, and state that since hypersplenism is a functional and not an anatomic diagnosis, the final diagnostic test is splenectomy.

The triad of cytopenia, rheumatoid arthritis, and splenomegaly, the Still-Chauffard-Felty syndrome is characteristic of the hypersplenic state. This syndrome was first reported as a distinct clinical entity by Felty[5] in 1924, and subsequently it has been shown that removal of the enlarged spleen produces beneficial hematologic results.

In the hemolytic syndrome we are indebted to Banti,[1] who produced hemolytic anemia experimentally and concluded that the spleen was the central feature of that disease, stating it was a "hemolytic splenomegaly" and suggested splenectomy as a therapeutic procedure. This was first performed by Micheli in 1911. It was later that splenectomy was done therapeutically for idiopathic thrombopenic purpura.

In the field of hemolytic diseases, there are diversified opinions regarding classification. This difficulty in grouping the hemolytic anemias in the adult is emphasized by Fowler.[6] Watson[16] has grouped those cases showing microcytosis as being familial, while those with macrocytosis are of the secondary or acquired type. Singer et al state that a change in the red cell fragility to hypotonic saline solution following splenectomy may give additional aid in differentiating the congenital from the acquired type, i.e., in the acquired group the red cells become less fragile after removal of the spleen. In differentiation, Fowler stresses the importance of the following features which favor the acquired type; onset usually later, more rapid course, less marked or absent red cell fragility, and a smaller percentage of reticulocytes. He reported 13 cases of which he termed idiopathic acquired hemolytic icterus, two of which had splenectomy, both with good response. Symptomatic hemolytic anemia, as reported by Singer and Dameshek,[12] often produces spherocytosis and increased red cell fragility and may present a "pseudomacrocytic" blood picture. They state that splenectomy may be valueless unless the underlying process, such as a dermoid cyst in one of their cases, can be removed.

Stickney and Heck[15] have reported twenty-two cases which they termed primary non-familial hemolytic anemia. Their cases were grouped as those showing microspherocytosis or increased red cell fragility and those showing neither. They felt that the better results, as regards splenectomy, were obtained in the group showing microspherocytosis. They further stated that agglutinins and hemolysins did not appear to play a significant role as far as the production of the hemolytic syndrome in their cases.

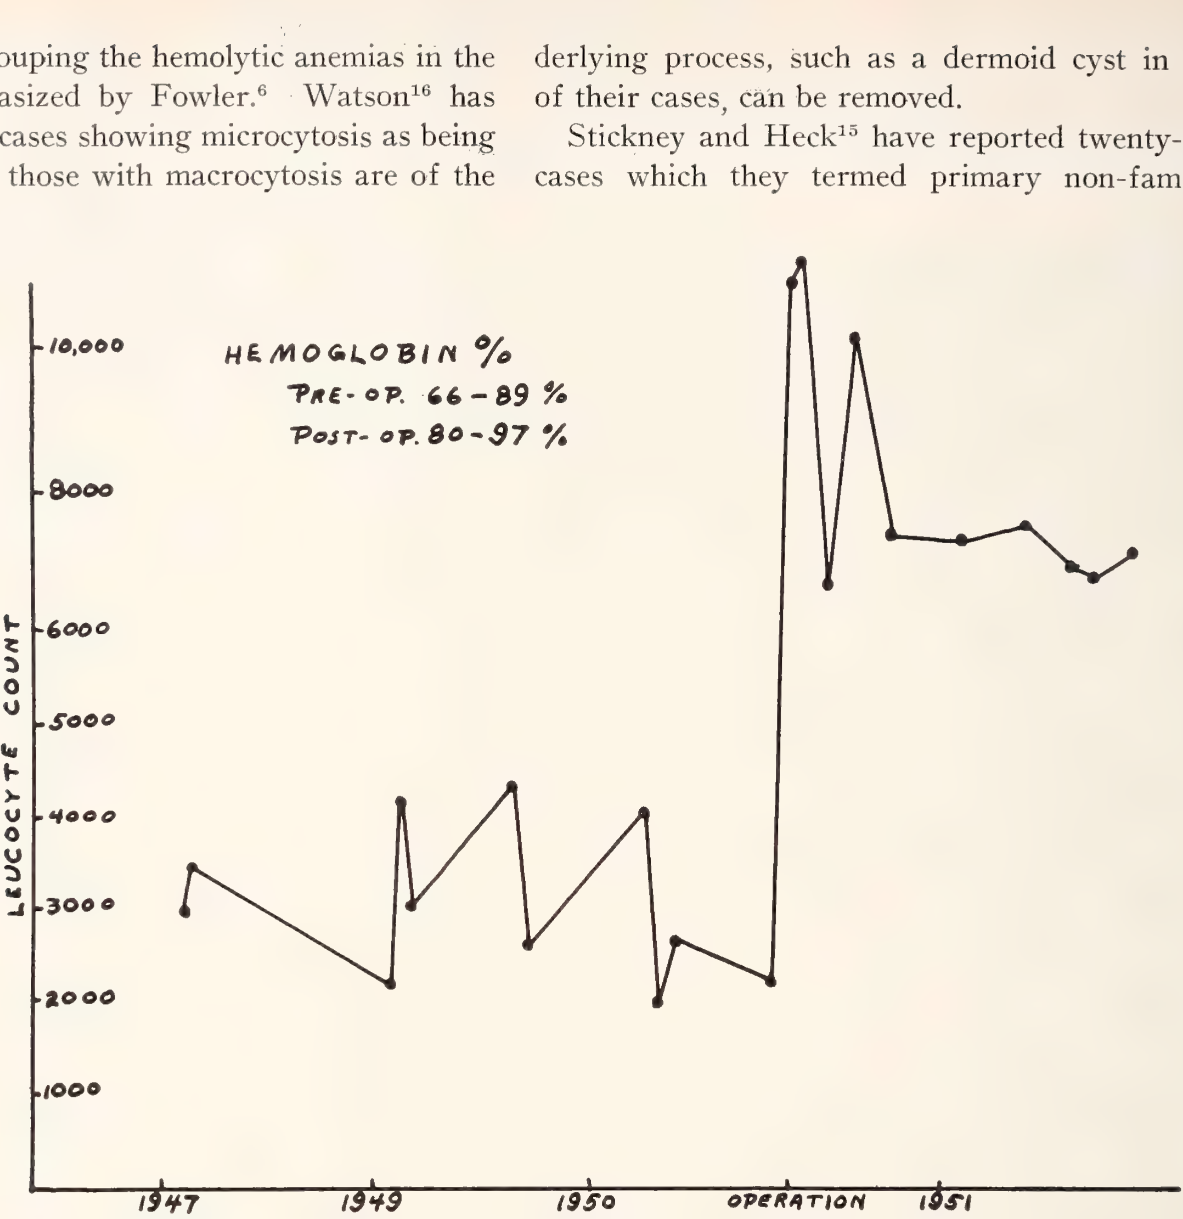

Fig. 1

Report of Cases

Case 1.—A sixty-three-year-old woman gave a history of rheumatoid arthritis of eleven years' duration. She was first seen in 1947 and at that time had white cell counts of 3,200 and 3,500 with 33 per cent polymorphonuclear cells and a hemoglobin of 77 per cent. A splenomegaly was noted at that time. She was seen again in 1949 and studies done then showed leukocytes 2,300 and 4,200 with polymorphonuclear cells from 31 to 39 per cent; platelets, icterus index, red cell fragility, and liver function tests were all normal. Splenectomy was advised but was withheld until the patient's general condition could be improved. She was placed on hematinics and given pentnucleotide to be continued at home. However, a short time later, she developed fever, chills, and a large area of cellulitis in the buttock area where she had received the injections. She was hospitalized and blood smears showed a leukemoid reaction, the bone marrow being normal. She was treated with the usual antibiotics and blood transfusions, and again splenectomy was advised.

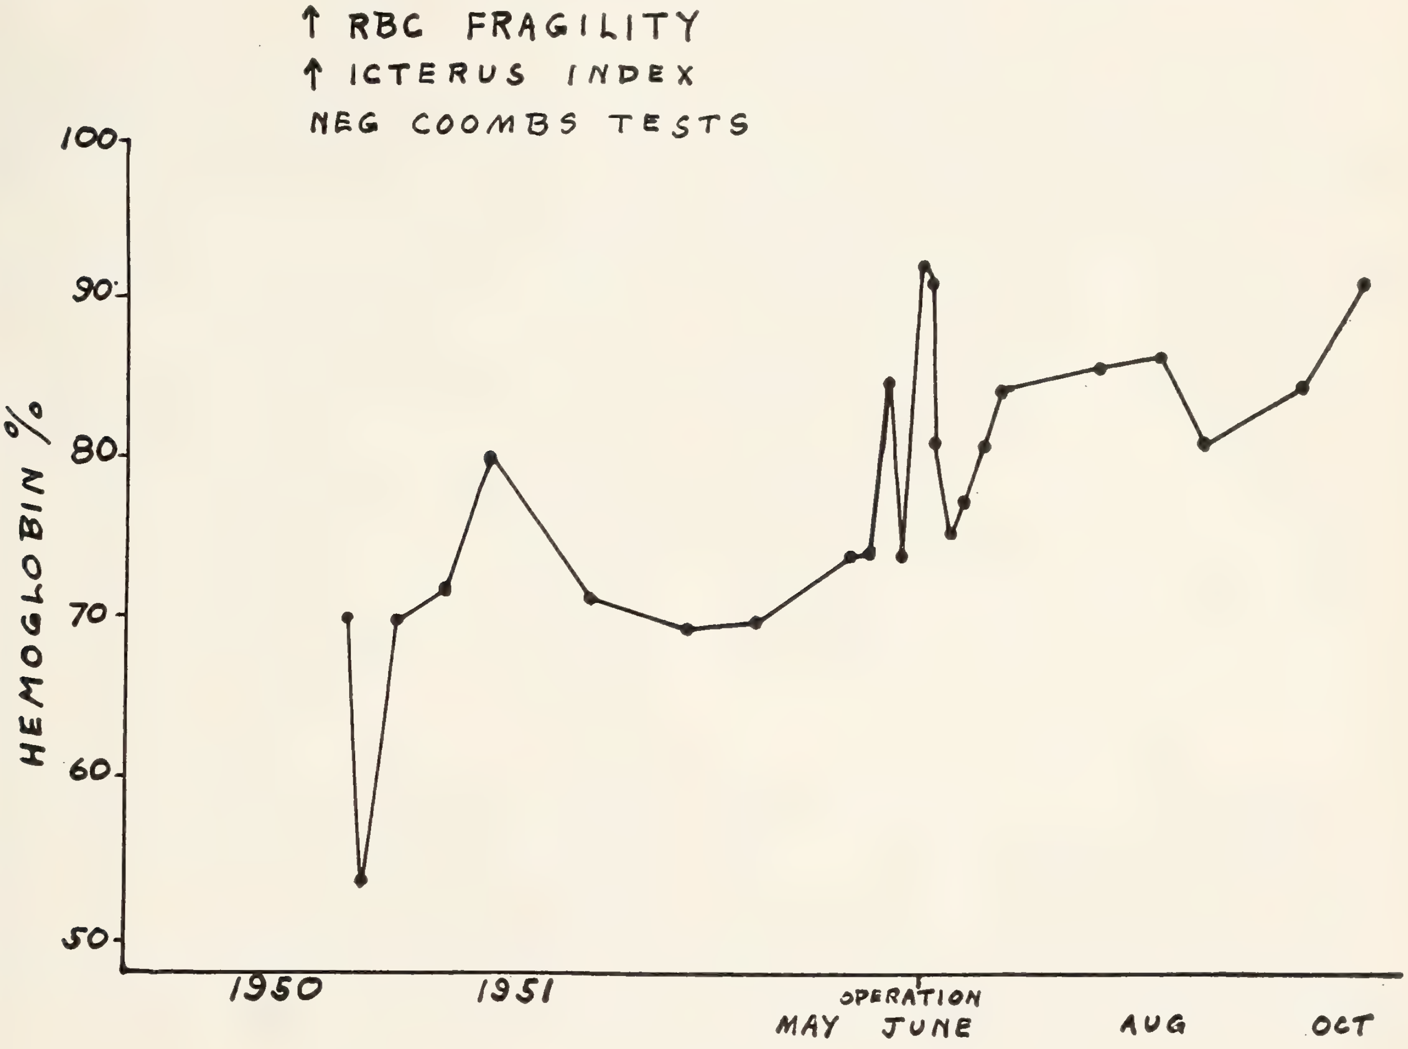

Fig. 2

In March, 1950, she was admitted again for transfusions because of her susceptibility to infections, the white count being 4,200 on this admission. Later in March, she developed an abscess in the right thigh which was drained, the leukocyte counts then being 2,050 and 2,700. In June, 1950, she was admitted for splenectomy. The bone marrow prior to operation was slightly hyperplastic. Preoperatively, the white count was 2,300 with 45 per cent polymorphonuclear cells and hemoglobin 89 per cent. The day after operation the white count was 11,150 with 91 per cent polymorphonuclear cells and the hemoglobin 97 per cent. Figure 1 shows the course of the leukocytes before and after operation. At the time of operation, a 660-gram spleen was removed along with a small accessory spleen in the hilar area. Histologically the spleen showed no phagocytosis of leukocytes. Since the operation, there has been only slight, if any, improvement in the arthritis.

Case 2.—A twenty-five-year-old white woman who was seen by her attending physician in July, 1950. She complained of nausea, weakness, flank pain and slight fever. On examination, an enlarged spleen was found and she was hospitalized. In her family history there was no evidence of anemia, jaundice, or splenomegaly. She was primigravida and her past medical history was non-contributory. Complete physical examination was negative except for the splenomegaly. Blood studies showed a hemoglobin of 70 per cent, white count 6,600, platelets 100,000, serum bilirubin slightly elevated with an indirect reaction of 2.4 mg., and red cell fragility with hemolysis beginning at 0.72 per cent and complete at 0.40 per cent. Stool urobilinogen was normal. Reticulocyte count was 9.8 per cent, and no free hydrochloric acid was found after gastric stimulation. Liver function studies were all normal. Bone marrow aspiration was reported as hyperplastic but non-diagnostic. It was felt she had possibly pernicious anemia and was given concentrated liver extract, folic acid, vitamin B_{12} and iron during the course of several months without any particular change in the blood state. Figure 2 shows the hemoglobin percentages during the course of her illness. In May, 1951, she was readmitted for further study. Again the only physical finding was the splenomegaly. At this time the hemoglobin was 74 per cent with slightly over 3,000,000 red cells, white count 9,900, reticulocyte count 3.7 per cent and platelet count over 200,000. On two occasions, there was a markedly increased red cell fragility with beginning hemolysis over 0.70 per cent. Serum bilirubin was slightly elevated and studies of red cell diameter were normal. The Coomb's anti-globulin test was negative on two occasions. Bone marrow was slightly hyperplastic. Liver function studies were again normal. No spherocytosis was demonstrated. Irregular agglutinins were not studied. The epinephrine test averaged 3,500,000 red cells, 8,900 white cells and 70 per cent hemoglobin prior to injection, with an average of 4,000,000 red cells, 20,000 white cells and 85 per cent hemoglobin following it. There was also a marked contraction of the spleen after injection. It was felt we were dealing with a primary hemolytic state as there was no evidence of any toxic or infectious agents or evidence of any primary disease with an associated hypersplenic state being present. At the time of operation a 957-gram spleen was removed which microscopically showed no evidence of erythrocyte phagocytosis. Following surgery, the hemoglobin percentages have varied from 75 to 92 per cent and the red cell count from 4,000,000 to over 4,500,000. Recheck of the red cell fragility two months postoperatively showed only a slight increase over normal values. She has been asymptomatic since surgery. The opportunity to check the relatives has not been obtained.

Discussion

The value of splenectomy in the hypersplenic state is confirmed by the present report. Hanrahan and Miller[7] in 1932 performed the first splenectomy in Felty's syndrome. In their case, the leukocyte counts ranged from 800 to 1,600 preoperatively and were 10,000 to 12,000 four months following surgery. Death occurred eighteen months after removal of the spleen, but the cause was not given. Hirschboeck has reported two cases of Felty's syndrome in which splenectomy was done, with the blood picture returning to normal in one. The second patient died six weeks postoperatively of portal vein thrombosis, but prior to operation the white count was 950 and after operation remained over 8,000. Dameshek and Estren[3] have also reported a case in a fifty-five-year-old woman who had 1,700 leukocytes which remained over 7,000 following splenectomy. Steinberg's report,[14] as well as that of others,[11,17] adds further evidence to the value of splenectomy in Felty's syndrome. Numerous authors have also reported the beneficial results of splenectomy in certain of the hemolytic states.

From the present report, the author feels that further emphasis should be placed on careful diagnostic evaluation, and the need of less conservatism in regard to the therapy of those cases which are included in the hypersplenic state. Radical, needless splenectomies certainly are to be condemned, as splenectomy is always a serious surgical procedure. However, Young et al[19] have stated that the chances of obtaining substantial benefit from splenectomy are great enough to justify recommending surgery in most cases even though it is impossible to predict which patients will respond favorably. Furthermore, according to Dameshek, if the diagnosis of hypersplenism is correct, splenectomy may be expected to cure the hematologic abnormalities in about 80 per cent of the cases.

Bone marrow depression as the cause of the selective cytopenias in the cases under discussion was not evident, as, in both, histologically, the marrow was slightly hyperplastic. This correlates with the findings reported by Steinberg.

No definite conclusion can be stated from these cases as evidence favoring only one or the other of the hormonal or phagocytic theories.

Summary

A review of the concept of hypersplenism has been presented with the emphasis on the review of pathologic physiology, diagnostic criteria, and the value of splenectomy.

Two cases of hypersplenism in which splenectomy has produced beneficial hematologic results have been reported.

FLUORIDATION OF WATER AND ITS RELATION TO REDUCTION OF DENTAL CARIES

WILLIAM A. JORDAN, D.D.S., M.P.H.

Minneapolis, Minnesota

FLUORIDATION of public water supplies is now widely accepted as a method for reducing the prevalence of dental caries. Of all the preventive methods in use, including toothbrushing, restriction in the consumption of concentrated sugar, and topical application of sodium fluoride, fluoridation offers the greatest hope for preventing caries because of its easy application for large numbers of people and its relatively low cost.

A long series of studies has shown that the controlled fluoridation of public water supplies as a means of reducing tooth decay is economical, safe, and effective. These studies, begun approximately thirty-five years ago, were initiated in an attempt to find the cause of dental fluorosis (mottling of the tooth enamel) in many areas of the United States.

Dr. Frederick McKay's reports on several western communities, including Colorado Springs, Colorado; Oakley, Idaho; Bauxite, Arkansas, and Britton, South Dakota, tell the story of finding the cause of mottled enamel, which was the excessive intake of fluoride in drinking water.[8] In 1931, the chief chemist of the American Aluminum Company, Mr. H. V. Churchill, in an analysis of water from Bauxite, first detected fluoride as a natural element of water. On Dr. McKay's suggestion, several communities where excessive fluoride was causing mottling of tooth enamel changed their water supply to fluoride-free water and thus eliminated dental fluorosis in the next generation of children.

In the United States today, dental fluorosis is most prevalent in Arizona, Colorado, South Dakota, and Texas. Endemic areas also are found in Arkansas, California, Idaho, Illinois, Indiana, Iowa, Kansas, Louisiana, Minnesota, Mississippi, Nevada, New Mexico, North Carolina, North Dakota, Ohio, Oklahoma, Oregon, South Carolina, Tennessee, Utah, and Virginia.

Practically all the community water supplies of Minnesota contain some natural fluoride, mostly less than .5 p.p.m. Approximately twenty-four communities have from .5 to .9 p.p.m. of fluoride in the water. Two communities report the ideal amount, 1 to 1.5 p.p.m. Four communities in Redwood and Meeker Counties have reported water analysis showing 2 or more p.p.m. of fluoride. In the early studies of mottled enamel, Graceville, Minnesota, showed evidence of excessive amounts of fluoride in the water supply. That community has changed the source of its water and the fluorosis picture has also changed.

Epidemiology of Fluoride and Dental Caries

It has been observed that wherever mottled enamel or fluorosis existed, there was a great reduction in the prevalence of dental caries (tooth decay). Studies were conducted by Dr. Trendley Dean[4] and his co-workers as to the relation of the amount of fluoride in the water and the degree of fluorosis as compared with the rate of dental caries. In the twenty-one cities studied, it was observed that the fluoride content in the water had a direct bearing on the severity of fluorosis of the teeth. Figure 1 shows that Lubbock, Texas, with a 4.4 p.p.m. of fluoride in the water, experienced a severe fluorosis condition in 60 per cent of the children. In Colorado Springs, Colorado, the water contained 2.5 p.p.m. of fluoride, and only 18 per cent of the children showed evidence of severe fluorosis. In Monmouth, Illinois, with a fluoride content of 1.7 p.p.m., no severe fluorosis was evident. With this amount of fluoride, Dr. Dean and his co-workers detected very little even of the mild type of fluorosis—a type that the average dentist not trained in this field would not be able to diagnose as such.

In these same studies it was also observed that there was a direct relation between the incidence of dental caries and the amount of fluoride present in the water. Where the water contained less than 0.5 p.p.m. of fluoride, the DMF rate (decayed, missing and filled permanent teeth) in children twelve to fourteen years of age was 725 teeth per 100 children, or 7.25 teeth affected per child. Figure 2 shows that cities with 0.5 to 0.9 p.p.m. of fluoride reveal a DMF rate of ap-

---

Dr. Jordan is Director, Division of Dental Health, Minnesota Department of Health.

proximately 4 teeth per child. In cities of 1 to 1.4 p.p.m. of fluoride, the rate was even less than 3 DMF teeth per child. Where the fluoride content of water exceeded 1.5 p.p.m., the caries rate was slightly less than in those where the fluoride content was from 1 to 1.4 p.p.m.

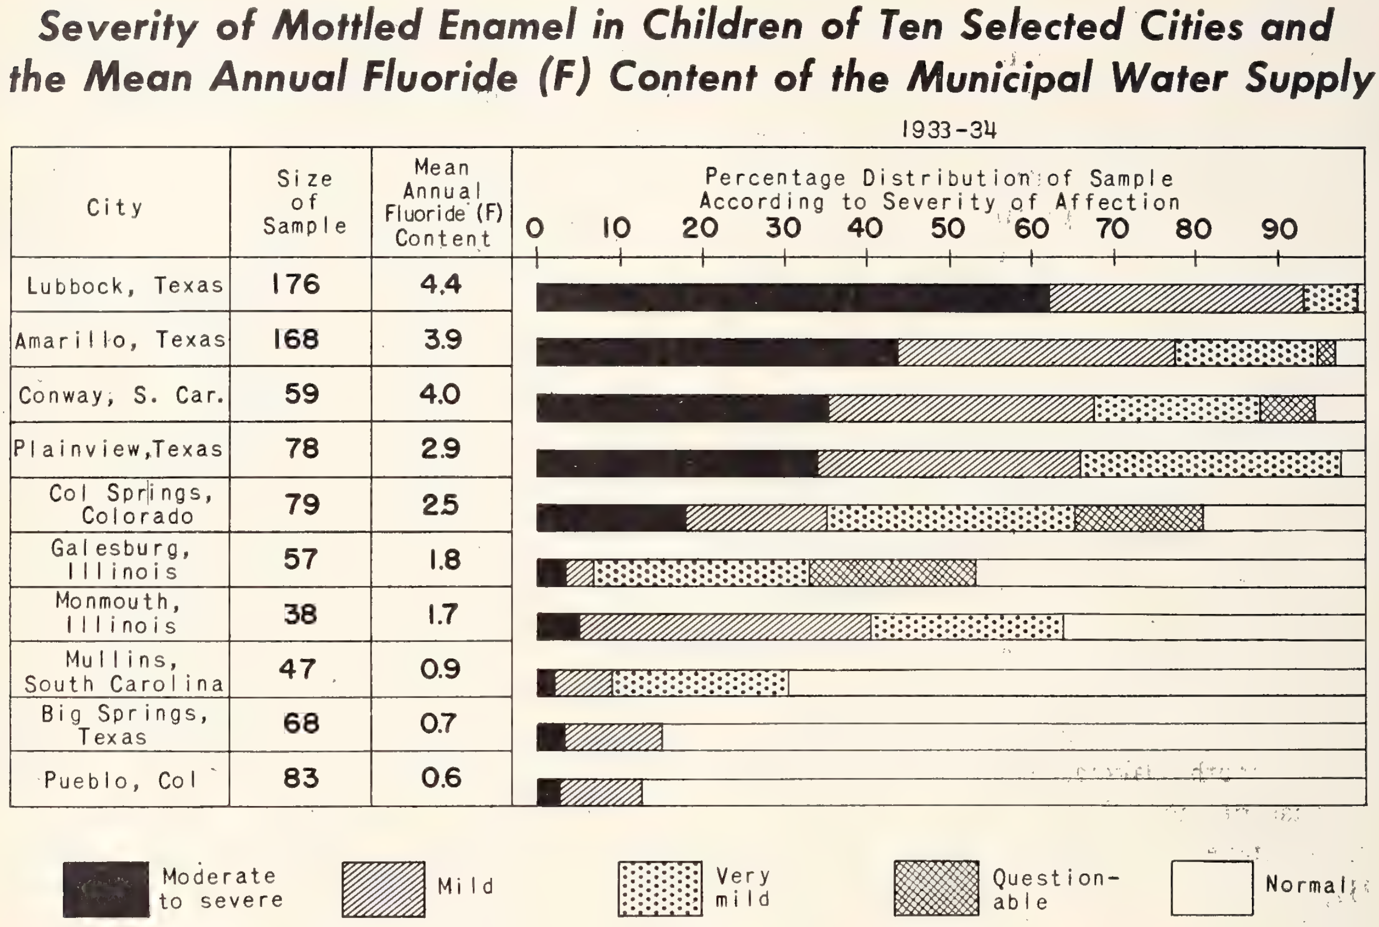

Fig. 1.

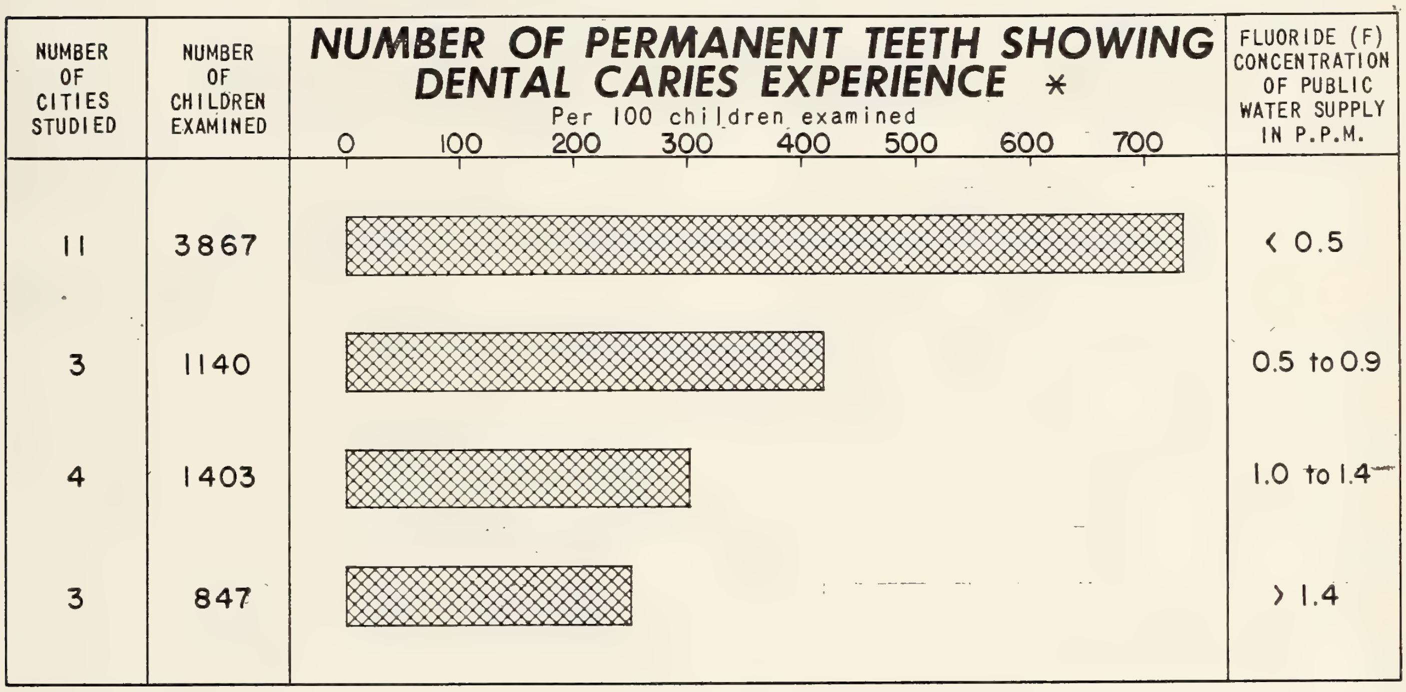
Figure 1 shows that fluorosis of the enamel is not evident at 1.7 p.p.m. or less, and in Figure 2 the lowest incidence of dental caries is shown in areas where the fluoride content of the water is 1 to 1.5 p.p.m. or more. On this basis Dr. Dean and the U. S. Public Health Service recommend that 1 to 1.5 p.p.m. of fluoride in the water ingested during the developmental period of the teeth (which is about the first ten years of the child's life) will reduce dental caries approximately 65 per cent, with no detectable fluorosis. Dr. Dean's studies further demonstrated that where fluoride is found naturally in the water one may expect:

1. About six times as many children having no dental caries experiences as in areas where little or no fluoride is found.
2. About 75 per cent decrease in loss of first permanent molar teeth.
3. Approximately 95 per cent less caries in the proximal surfaces of the four upper incisors.

Dr. Wallace Armstrong[1] of the University of Minnesota demonstrated that a sound tooth had twice as much fluoride content in the enamel as a carious tooth. He further demonstrated that a tooth affected by fluorosis had twice the amount of fluoride as a sound fluorosis-free tooth.

Minnesota's Fluoride Areas

Minnesota does not have many areas with sufficient fluoride to reduce dental decay. In a few small communities in the Meeker and Redwood County area, the water supplies reveal 1 or more p.p.m. of fluoride. In April, 1951, the Minnesota Department of Health made dental examinations of the eleven to thirteen age group in Walnut Grove and Milroy.[9] Both these communities had a fluoride content of 2 p.p.m. These dental examinations were compared with those on the same age group in Hinckley and Grand Marais where the fluoride content was insignificant at the time of the examination. Table I reveals that the children born and residing continuously in the villages of Milroy and Walnut Grove had a DMF rate of 1.8 teeth per child as compared with rates of 7.14 and 6.43 in Hinckley and Grand Marais, respectively. Children born in Redwood County and attending school in Milroy or Walnut Grove reveal a rate of 3.36 teeth per child.



* Dental caries experience is computed by totaling the number of filled teeth (past dental caries), the number of teeth with untreated dental caries, the number of teeth indicated for extraction, and the number of teeth missing (presumably because of dental caries).

Fig. 2. Amount of dental caries (permanent teeth) observed in 7,257 selected twelve-to-fourteen-year-old, white, school children in twenty-one cities of four states; classified according to the fluoride concentration of the public water supply. From Dean, H. T.; Arnold, F. A., Jr., and Elvove, E.: Pub. Health Rep., 57:1155-1179 (Aug. 7) 1942.

TABLE I. COMPARISON OF CARIES EXPERIENCE IN THREE MINNESOTA AREAS
Milroy and Walnut Grove water supplies contain 2 to 2.1 p.p.m. fluoride

	Grand Marais November, 1950	Hinckley October, 1950	*County** Milroy-Walnut Grove April, 1951	*Village*** Milroy-Walnut Grove April, 1951
Group Examined	11-13 years	11-13 years	Grades 6-8	Grades 6-8
Number in Group	113	108	195	32
Per cent of Children with DMF Teeth	98.2	97.2	75.9	65.6
Average DMF Teeth	7.14	6.43	3.36	1.80
Average Lost Permanent Teeth	0.38	0.72	0.15	0.13

**Milroy-Walnut Grove children in grades 6-8, inclusive, who have lived all their lives in Milroy or Walnut Grove.

Controlled Fluoridation

Controlled studies were developed to determine if fluoride added to fluoride-free water in controlled amounts would result in the same reduction in dental caries as natural fluoridated water. Several studies were inaugurated in the United States and Canada on a ten-year basis. Most of these studies have now been under way for more than five years. The studies in Grand Rapids, Michigan, and in Newburgh, New York, have been watched closely. In each case annual physical and dental examinations have been made on all children in the age group 3-17 years. The results after five years' application of 1 p.p.m. of fluoride to the water supply of Grand Rapids, Michigan, is revealed in Figure 3.[5] Muskegon was the control city for this study. Both cities receive their water supply from Lake Michigan. These two cities in turn are compared with Aurora, Illinois, which has a water supply showing a content of 1.2 p.p.m. of fluoride naturally. The DMF rate of the lower age groups in Grand Rapids after five years parallels the rate in Aurora. Similar conclusive results have been published from Newburgh.[2] The older children receive some benefits, but the greatest reduction is achieved when the child from birth drinks water containing 1 to 1.5 p.p.m. of fluoride and remains in residence until the crowns of the permanent teeth are fully formed—a period of approximately ten years. Following that period the benefits are lasting regardless of where the individual resides.

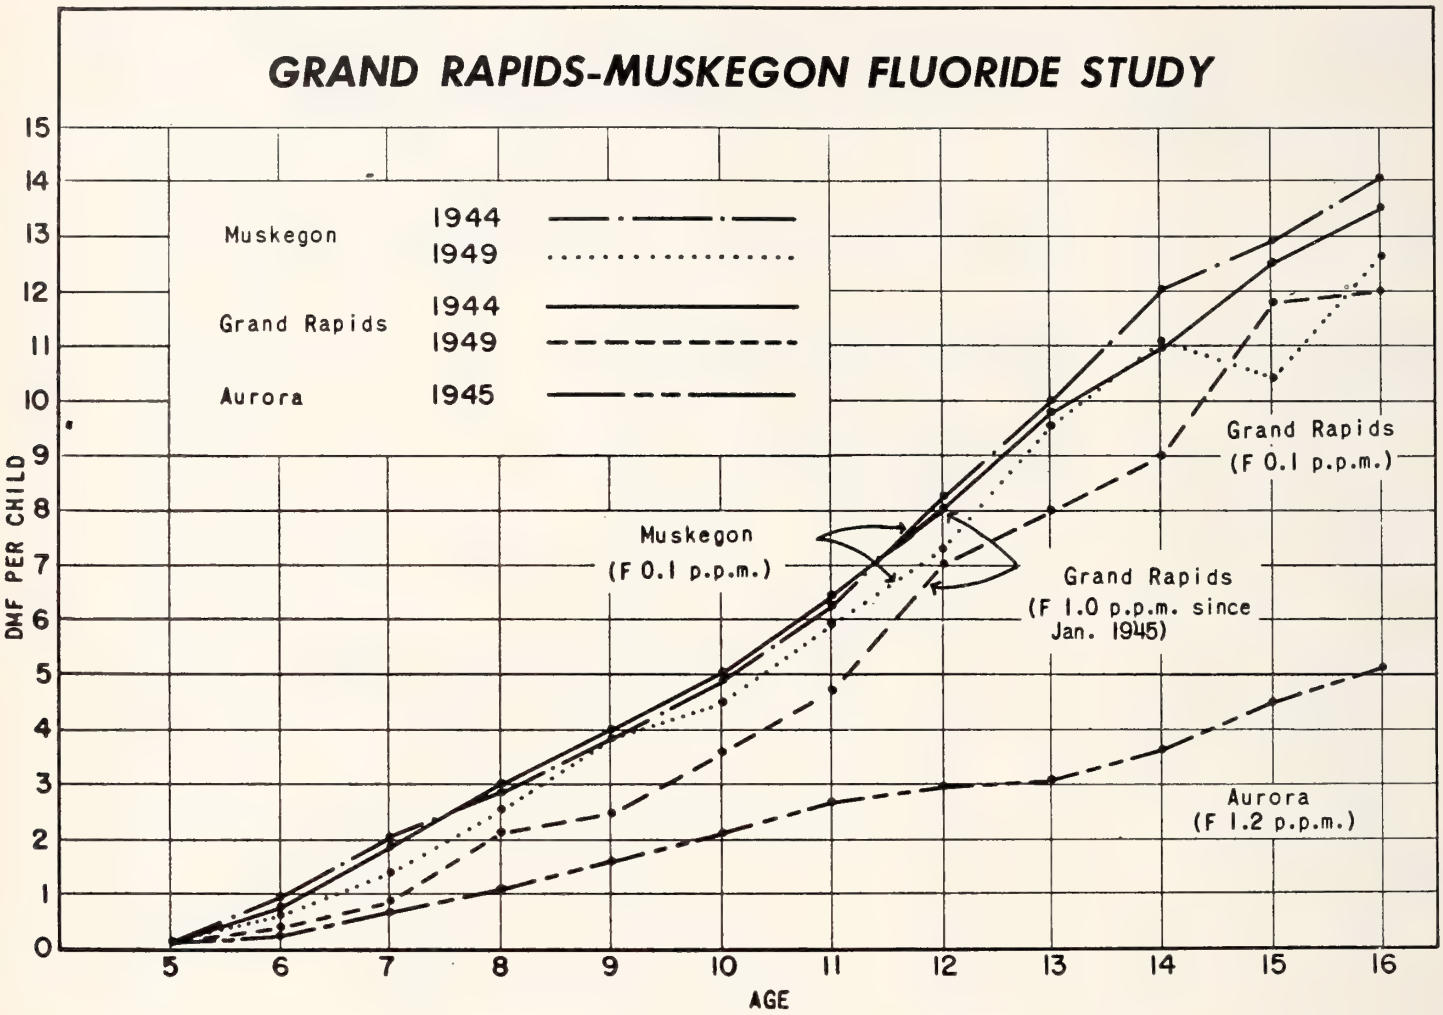

Fig. 3.

Fuoride in water is colorless, odorless, and tasteless. In Minnesota the State Health Department advocates, wherever a community wishes to proceed with a fluoridation program, that 1.2 p.p.m. of fluoride be added to the water supply. Members of the Divisions of Dental Health and Municipal Water Supply of the Minnesota Department of Health are prepared to assist any community interested in a water fluoridation program. Public health engineers in the eight health districts of the state are likewise prepared to give local communities consultation and advice on this subject.

HEALTH DISTRICT OFFICES AND PUBLIC HEALTH ENGINEERS

Health District	*Headquarters*	*Public Health Engineer*
I	Bemidji	Mr. Robert H. Pinther
II	Mankato	Mr. Elmer A. Huset
III	Rochester	Mr. F. J. Kilpatrick
IV	Duluth	Mr. H. G. Formo
V	Worthington	Mr. A. C. Larson
VI	Minneapolis	Mr. Daniel L. Baer
VII	Fergus Falls	Mr. Frederick Heisel
VIII	Little Falls	Mr. Andrew J. Starin

Types of Installations

There are three methods of feeding fluoride into the water supply—solution feed, dry volumetric, and dry gravimetric. The solution feed method is adapted to small communities. The volumetric feeder will serve the water supply of communities between 20,000 and 50,000 population. The gravimetric feeder is generally used in larger cities. Solution feeders may be installed for $500 or more, according to the capacity and auxiliary equipment needed. Dry feeders cost considerably more. Public health engineers should be consulted regarding the type best suited to each community. The manufacturers of this equipment state that they will be happy to give consultation on cost and installation. All equipment is automatically controlled and equipped with all safety devices in accordance with state laws.

Fluoride Compounds Used

Sodium fluoride is being used in many water fluoridation projects because it is readily available and convenient to use, dissolves easily, and has been the subject of extensive studies on toxicity and physiological effects.

Sodium silicofluoride (sodium fluosilicate) is one of the most economical compounds. It provides available fluoride at from one-third to one-half the cost of that obtained from sodium fluoride.

Hydrofluosilicic acid, while more costly than sodium silicofluoride, can be fed directly into water supplies without considering solubility and with the least handling.

Hydrofluoric acid is being used in one city—Madison, Wisconsin. It is dangerous to handle, corrosive, and not recommended.[7]

Fluoride is placed in a water supply in a manner similar to the addition of other elements used in water departments.

Testing Fluoride Content

A colorimetric testing device has been developed to determine the amount of fluoride in the water to within 0.20 parts of fluoride per million parts of water. The average water works operator in a small community can make the determinations with reasonable accuracy. These tests are made several times a day at the beginning of the program and are rechecked by tests made by district or state health departments. Occasional check of tap water will determine the fact that the fluoride has reached all areas of the water system.

Cost of Fluoridation Programs

For a cost of 5 to 14 cents per capita per year, the next generation of children can have better dental health.[6] The Red Lake Falls installation for a population of 1,700 cost about $700, including equipment, electrical installations, plumbing, jars for solution, testers, and cabinet. The annual maintenance is estimated at 5 cents per capita.

TABLE II. ECONOMICS OF FLUORIDATION*

MADISON—.005 p.p.m. Fluorine			
Dental Decay Experience and Expense Through Average Age 16			
Baby Teeth	Avg. DMF	units	10.28 at $ 3.00=$30.84
Perm. Teeth	Avg. DF	units	16.66 at $ 4.00=$66.64
	Avg. M	units—restored	3.21 at $25.00=$80.25
	Avg. M	teeth—extracted	1.07 at $ 5.00=$ 5.35
Total average dental expense per person $183.08			
UNION GROVE—1.2 p.p.m. Fluorine			
Baby Teeth	Avg. DMF	units	3.12 at $ 3.00=$ 9.36
Perm. Teeth	Avg. DF	units	4.30 at $ 4.00=$17.20
	Avg. M	units—restored	0.48 at $25.00=$12.00
	Avg. M	teeth—extracted	0.16 at $ 5.00=$ .80
Total average dental expense per person $39.36			
Cost of Fluoridation ...... 25 cents per year × 16 = $4.00			
Saving of $143.72 or $35.93 for $1.00 invested			

*Dane County Dental Society, Wisconsin, Flourine Committee.

The total daily cost of adding sodium fluoride to the water supply of an average town of 10,000 is about $2.25. If sodium silicofluoride can be used, the daily cost may be about 75 cents. On a per person basis, sodium fluoride costs about 11 cents per year, silicofluoride about 5½ cents. Amortized over a twenty-year period, the annual cost of equipment for feeding fluoride into the water supply is almost negligible.

At the rate of 14 cents per person per year and in a life span of 75 years, an individual would pay $10.50 for two-thirds less dental decay and two-thirds less dental bills. Table II shows a comparative study of dental cost for a sixteen-year-old individual in Madison, Wisconsin, which had fluoride-free water, and for a similar individual in Union Grove, Wisconsin, which has 1.2 p.p.m. of fluoride. The dental expenditure of the Union Grove sixteen-year-old is approximately 78 per cent less than that of his counterpart in Madison. (Fluoride is now being applied to the water in Madison.)

For an annual investment per person of the price of one candy bar or a little more, the community can bring greatly improved dental health to its younger children. The children of today are the adults of tomorrow. As the fluoridation program continues, more and more individuals will benefit until the whole population is protected.

Dr. A. L. Russell[10] reports that adults twenty to forty-four years of age show continued

TABLE III. DEATH RATES PER 100,000 POPULATION FROM SELECTED CAUSES IN WISCONSIN CITIES WITH VARYING CONCENTRATIONS OF FLUORIDE IN PUBLIC WATER SUPPLIES, 1945-1949*

City	Green Bay	Stevens Point	Sheboygan	Sheboygan .03 p.p.m. (pre-fluoridation 1940-44)
Fluoride Concentration in Water Supply	2.5 p.p.m.	0.02 p.p.m.	1.2 p.p.m.	
Leading Causes of Death				
Heart	279.7	298.5	340.9	311.0
Cancer	131.6	136.2	137.7	148.1
Cerebral hemorrhage	103.3	77.0	124.2	97.9

Influenza	8.2	2.4	4.5	8.4
Appendicitis	5.2	3.6	2.3	4.4

*Source: Wisconsin State Board of Health, continuous resident data.

benefits of fluoridated water. Comparisons were made between the age groups twenty to forty-four in Colorado Springs and persons of similar age in Boulder, Colorado. The water supply of Colorado Springs contained 2.5 p.p.m. of fluoride, while Boulder water was fluoride-free. Only those adults who were born and maintained a continuous residence in their respective communities were involved. Dental examinations showed that the group in Colorado Springs had a 60 per cent lower dental decay rate than the same age group in Boulder. The Boulder natives had lost three to four times as many permanent teeth from dental caries as the natives of Colorado Springs.

Today the controlled fluoridation program as a means of reducing dental caries is approved by the:

American Dental Association
American Association of Public Health Dentists
State and Territorial Dental Directors Association
State and Territorial Health Officers Association
American Public Health Association
U. S. Public Health Service
American Water Works Association
American Medical Association
Minnesota State Dental Association
Minnesota Department of Health

The controlled fluoridation of domestic water is more beneficial than the natural occurrence of fluoride in the water, because with controlled fluoridation, the public is assured that a constant amount of fluoride, 1.2 p.p.m., is in the water at all times. Natural fluoridated water varies with the seasons. The controlled program also assures the public of reduction of dental caries without fluorosis.

There is no evidence that fluoridated water contributes to the increase of various diseases (Table III).

Observations on the 3,000,000 people using water with 1.0 to 8 p.p.m. of fluoride in the western states area from South Dakota down through Texas give assurance that fluoridated water does not create any adverse physical defects other than fluorosis on the dental enamel where fluoride is present in excessive amounts. In that area:

1,000,000 people use water containing 1.0—1.5 p.p.m. of fluoride
900,000 people use water containing 1.6—2.0 p.p.m. of fluoride
600,000 people use water containing 2.1—3.0 p.p.m. of fluoride
100,000 people use water containing 3.1—5.0 p.p.m. of fluoride
40,000 people use water containing 5.1—or higher p.p.m. of fluoride

Drs. C. P. Cox and David B. Ast state that acute morbidity, manifested by increased salivation and vomiting, may be caused by 0.25 gm. sodium fluoride.[3] This quantity in an 8-ounce glass of water represents 1,000 p.p.m. of sodium fluoride or about 450 p.p.m. of fluoride. To obtain this concentration would require more than four tons of sodium fluoride per million gallons of water treated, which is obviously not possible in a program of water fluoridation, even if gross negligence occurred.

Approximately 140 communities within the United States are operating a controlled fluoridation program at the present time. Some of the larger cities that have started or are in the process of starting such a program are Philadelphia, Pennsylvania; Baltimore, Maryland; San Francisco, California; Saint Paul, Minnesota; Madison and Milwaukee, Wisconsin, and Washington, D. C.

In Minnesota, thirteen communities are now adding fluoride to their water supply. They are Red Lake Falls, Thief River Falls, Fergus Falls, Montevideo, Fairmont, Winnebago, West Concord, Ely, Granite Falls, Hallock, Arlington, Benson, and Hutchinson. At least fourteen other communties are known to have ordered equipment and will start adding fluoride in the near future. All fluoridation plans for Minnesota communities must be approved by the Division of Municipal Water Supply, Minnesota Department of Health.

AUTOPSIES REPORTED ON MINNESOTA DEATH RECORDS

J. W. BROWER, M.A., and E. W. STOREY, M.S.
Saint Paul, Minnesota

An awareness of a growing interest on the part of physicians in autopsies prompted a limited survey of the extent to which the postmortem examination is performed in Minnesota. While the restricted scope of the analysis makes for inconclusiveness, it is nevertheless felt that the results of the study may be indicative of present trends.

Source of Data

The question "Was there an autopsy?" first appeared on the Minnesota death certificate in the 1918 issuance of these forms. Since 1920 the autopsy question has continuously been a part of the Minnesota record of death. On the forms prescribed by the Minnesota State Board of Health for the years 1920 to 1941, the autopsy item was represented merely by the question "Was autopsy performed?" From 1941 to 1947 the medical certification portion of the death record provided space for "Major findings of operation . . . of autopsy." The item was returned in 1947 to the phrasing used from 1920 to 1941, and in the new uniform certificate of death, adopted in 1950 and presently in use, the item was further simplified to appear thusly:*

20. Autopsy?
Yes ☐ No ☐

For this study a tabulation of the responses to the autopsy question on the records of death occurring in Minnesota during the six-month period, April 1 through September 30, 1951, was made. However, since the greater portion of deaths occurs in the cities of Minneapolis, Saint Paul, and Duluth, a comparison was drawn, as shown in Table I, with the data contained in the death records of these three cities only for the comparable six-month periods in the years 1921, 1931, and 1941. It will be observed that the increase in number, as computed percentage-wise, is more pronounced between the years 1921 and 1931, being particularly noticeable in the data for the City of Duluth, but the gain between 1941 and 1951 is relatively insignificant. Saint Paul actually had a slight percentage loss over the comparable six-month period in the year 1941.

TABLE I. A THREE-CITY COMPARISON OF AUTOPSIES PERFORMED

Cities	Deaths—All Causes				Autopsies Performed				Per Cent of Cases Autopsied			
	1921	1931	1941	1951	1921	1931	1941	1951	1921	1931	1941	1951
Total for three cities	3,572	4,561	4,620	5,171	419	1,120	1,167	1,573	11.7	24.6	25.3	30.4
Minneapolis	1,980	2,538	2,576	2,819	230	574	514	785	11.6	22.6	20.0	28.2
Saint Paul	1,147	1,459	1,479	1,703	171	399	460	526	14.9	27.3	31.1	30.8
Duluth	445	564	565	649	18	147	193	252	4.0	26.1	34.2	38.8

The 1951 Analysis

A total of 13,866 deaths occurred in the state during the six-month period, April 1 through September 30, 1951, covered by this study. And 2,274 autopsies (16.4 per cent of the total) were performed on these deaths. No autopsy was reported in 8,199 deaths (59.1 per cent of the number), while the information was omitted on 3,393 records, representing 24.5 per cent of all deaths. The factors analyzed include geographic distribution, autopsies in hospitals, autopsies in medical certifications by physicians and coroners, and autopsy variations by cause of death.

Geographic Distribution

Table II shows that the largest number of autopsies was performed in Minneapolis. Of the deaths studied 20.3 per cent occurred in Minneapolis, while 35.0 per cent of all autopsies were done there. It will be noted that 28.2 per cent of all Minneapolis deaths were autopsied. The largest proportion of autopsies, for an

Saint Paul C.	100.0	30.8	51.3	17.9
Duluth C.	100.0	38.8	48.1	13.1
Rochester C.	100.0	4.3	5.0	90.7
Fort Snelling VA Hospital	100.0	74.9	25.1	0.0
Other urban areas	100.0	9.6	67.0	23.4
Other rural areas	100.0	4.2	68.9	26.9

entire city, 38.8 per cent of all deaths, was found in Duluth. Less than 10.0 per cent of the deaths occurring in urban areas outside Minneapolis, Saint Paul and Duluth were autopsied. On the basis of the affirmative answers appearing on the death certificates received from the rural areas of Minnesota, less than 5 per cent of all deaths were autopsied. The Veterans Hospital at Fort Snelling, however, performed autopsies on 74.9 per cent of its deaths.

Autopsies in Hospitals

For analysis purposes, hospital and institutional deaths were grouped into four categories: general hospitals, including maternity homes and nursing homes offering medical and nursing care; state hospitals for the mentally ill; tuberculosis sanatoria, and veterans hospitals. The study revealed that 77.4 per cent of all autopsied deaths, as shown in Table III, occurred in general hospitals, 3.4 per cent in state hospitals, 1.8 per cent in tuberculosis sanatoria, 6.3 per cent in veterans hospitals, and 11.1 per cent took place outside of these institutions.

Veterans hospitals autopsied 75.0 of their deaths; tuberculosis sanatoria, 47.1 per cent; general hospitals, 23.3 per cent; and state hospitals, 16.2 per cent. Autopsies were performed on only 4.5 per cent of all deaths occurring outside of these institutions.

TABLE III.
AUTOPSIES IN HOSPITALS

Place of Death	All Deaths	Was Autopsy Performed?		
		Yes	No	Not Stated
Number:	13,866	2,274	8,199	3,393
General hospitals	7,536	1,759	3,898	1,879
State hospitals	476	77	270	129
Tuberculosis sanatoria	87	41	42	4
Veterans hospitals	192	144	48	—
Non-hospitalized	5,575	253	3,941	1,381
Per Cent of State Total:	100.0	100.0	100.0	100.0
General hospitals	54.3	77.4	47.5	55.4
State hospitals	3.4	3.4	3.3	3.8
Tuberculosis sanatoria	0.6	1.8	0.5	0.1
Veterans hospitals	1.4	6.3	0.6	0.0
Non-hospitalized	40.3	11.1	48.1	40.7
Per Cent by Type of Hospital:	100.0	16.4	59.1	24.5
General hospitals	100.0	23.3	51.7	25.0
State hospitals	100.0	16.2	56.7	27.1
Tuberculosis sanatoria	100.0	47.1	48.3	4.6
Veterans hospitals	100.0	75.0	25.0	0.0
Non-hospitalized	100.0	4.5	70.7	24.8

Autopsy information was omitted on 25.0 per cent of general hospital deaths, 27.1 per cent of state hospital deaths, 4.6 per cent of the tuberculosis sanatoria, and 24.8 per cent of the non-hospitalized deaths. The veterans hospitals reported the information for all deaths.

Autopsies in Medical Certification by Physicians and Coroners

Physicians certified 87.6 per cent of the causes of death in the group under study. They certified 88.4 per cent of all deaths on which autopsies were performed. As shown in Table IV, 16.6 per cent of the deaths certified by physicians and 15.3 per cent of the deaths certified by coroners were autopsied.

The Causes of Death Reported in Autopsy Cases

With reference to the various causes of death, there is apparently a wide variation in the proportion of autopsies performed (Table V). For example, 55 per cent of the maternal deaths were autopsied. Deaths due to intracranial vascular lesions, general arteriosclerosis, hypertension without mention of heart disease, and suicide were autopsied in less than 10.0 per cent of the cases reported. Autopsies were done in over one-third of the deaths due to infective and parasitic diseases, diseases of the digestive system, nephritis and nephrosis, congenital malformations, and homicide. The groupings of the causes of death represent those in which there are particular public interest, including the leading causes of death for the State.

TABLE IV. AUTOPSIES IN MEDICAL CERTIFICATIONS

All other causes	976	214	516	246	100.0	21.9	52.9	25.2

Summary and Conclusions

1. A query regarding autopsy performed has appeared on Minnesota death records since 1918.

2. The findings of this study indicate that approximately 16 per cent of all Minnesota deaths are autopsied.

3. A large proportion of the autopsies is performed in the metropolitan areas of Minneapolis, Saint Paul, and Duluth.

4. Autopsies are most common in patients hospitalized in general hospitals or veterans hospitals.

5. There is wide variation in the proportion of autopsies among the various causes of death.

6. There is need for more complete response to the autopsy query on the death certificate. This study indicates that no reply was given on almost 25 per cent of the cases. Physicians are urged to supply this information in the medical portion of the death record. It is a part of the *complete* medical certification.

HISTOPLASMOSIS AND TUBERCULOSIS

Histoplasmosis must be taken into account in all routine x-ray surveys of population and differentiated from tuberculosis despite superficial similarities. Carefully controlled studies of the etiology of histoplasmosis in relation to conditions that vary geographically are very much needed.—G. ARNOLD CRONK, M.D., *New York State Journal of Medicine,* August 15, 1951.

President's Letter

THE ODDS ARE TWO TO ONE

The odds are two to one against doctors being good citizens.

If that startles you, consider the fact that only 36 per cent of the nation's physicians discharge one of the basic obligations of citizenship—exercising their right to vote.

During recent years, the medical profession has made aggressive entry into politics in order to keep politics out of the medical care picture. Physicians have developed an alert, analytical attitude toward legislative proposals and governmental agency functionings which affect the practice of medicine and, by inescapable progression, the health of the nation.

The medical profession has gone a step further than watchfulness and self-apprisement: through a gigantic and interlocking educational program, physicians have sought to inform the general public on these legislative and economic matters, which are of great personal significance by virtue of their impingement upon such individual prerogatives as the right to select and retain a family doctor.

The educational campaign has been as sharply depicted as a blackboard lesson, with emphasis on the economics of medical care, its close correlation, through the principle of free choice and personal initiative, with the entire democratic structure, and the inevitable decline in quality and availability that would result from governmental interference in the present medical care system.

The family doctors of America have become almost expert in legislative symptomatology and the diagnosis of dangerous "fringe" bills that could cause epidemics of sociological ill health.

And yet, we continue to fail in the important—the vital—duty of registering and voting at elections on all governmental unit levels. Thirty-six per cent of the nation's physicians is not a representative number; nor will it be possible for the load of good citizenship to be carried by only one out of every three physicians. Exercising the right to vote for capable and responsible officials helps to make the good doctor a good citizen.

THE PRESIDENT'S COMMISSION ON HEALTH NEEDS

PRESIDENT TRUMAN'S appointment on December 29, 1951 of a Commission on the Health Needs of the Nation to "make a critical study of our total health requirements, both immediate and long term and (to) recommend courses of action to meet those needs" immediately raised the question in many minds as to why. Are the health needs of the people today in such a state as to warrant the expenditure of defense funds to carry on an intensive year's study of such a many faceted subject?

When we consider that President Truman's answer to the health needs of the nation has been, in part at least, the socialization of medical care through compulsory government health insurance and that his efforts along this line have not been successful, we are inclined to agree that the placing of a limit of one year on the life of the committee has significance. It certainly will eliminate the question of compulsory government health insurance from the coming presidential election campaign. Is it possible that he prefers to approach that campaign with the issue of the socialization of medical care eliminated? We, for our part, feel that this will be for the best. The socialization of medical care should not be a plank in any political party platform, whereby it might be swept into the economy along with other political issues. However, voters who are opposed to the extension of socialism in government to the inclusion of medical care nevertheless will be mindful of the present administration's stand on this issue.

Dr. Gunderson's declining to serve on the committee was because he believed that its majority membership and objectives indicated it was "an instrument of practical politics." He doubtless knows whereof he speaks. The chairman of the committee, Dr. Paul Magnuson, is a native of Saint Paul, whose abilities as a Chicago surgeon and executive in the Veterans Administration are well known. He stands well in the opinion of the medical world and his remark as quoted in *Time* (January 14), that we would all be better off if the AMA hierarchy devoted as much time to care of their patients as they do to political maneuvering was unfortunate, to say the least.

That medical care in certain cases may be very costly is universally recognized. This was emphasized as far back as 1929 when the report of the Committee on the Cost of Medical Care was made. The cost of sickness has always been catastrophic in certain instances. That insurance is necessary to protect against today's high cost of sickness is recognized by the profession as well as the public. This is evidenced by the phenomenal increase in the number of hospital and medical insurance policies sold in recent years.

This type of insurance, and not government insurance involving the taking over of the medical care of our citizens, is the answer of the profession as to the present Health Needs of the Nation. These voluntary policies should also, if possible, be written to cover chronic illnesses which can be particularly catastrophic.

The cost of medical care has increased along with every other commodity in recent years. It has not, however, increased more in proportion than other costs. The blame for this cannot be laid at the door of the medical profession but lies more justly with Congress and the administration. Less unnecessary government spending and lower taxes would enable the people to give better care for their medical needs.

NATIONAL SOCIETY FOR CRIPPLED CHILDREN AND ADULTS, INC.

ONE REASON why life in these United States is on a higher plane than anywhere else in the world is the existence of voluntary organizations like the National Society for Crippled Children and Adults, which are supported for the most part by small contributions of American citizens simply out of a kindly concern for their unfortunate fellow beings. Somehow, a dollar contributed out of kindness of heart seems to have a greater value than a tax dollar collected involuntarily. For "the gift without the giver is bare." We would regret to see the many activities for the care of the handicapped now being conducted by these national organizations taken over by governmental agencies. As a matter of fact, we resent the encroachment by the government in certain of these fields which are well supported by voluntary contributions.

The National Society for Crippled Children and Adults was founded in 1921. Since 1934, it has conducted each year an Easter Seal appeal for support. This year, between March 13 and April 13, Easter Seals will be sent to 29 million homes, and opportunity will be given to recipients to contribute to the Society's 10 million dollar program.

The National Society has some 2,000 affiliated Easter Seal societies which receive the support of physicians at the local level, whereas the National Society receives the co-operation of liaison officers of the American Medical Association.

The activities of the societies consist largely in the provision of physiotherapy facilities and trained therapists, psychologists, medical social workers and educators to complement the services of the physician.

LIFE MEMBERSHIP IN MEDICAL ORGANIZATIONS

According to a provision of the constitution of the Minnesota State Medical Association adopted in 1946, members of component county societies who have been active members for forty years and have attained the age of seventy may apply for *life memberships* through their component county society to the Council of the Association. A life membership entitles the possessor to all the rights and privileges of active membership except subscription to Minnesota Medicine,* and he is exempt from dues.

To enable a member to take advantage of this active membership without dues the county medical society of which he is a member must also provide for a life membership free from dues and Hennepin County and Ramsey County medical societies have done just that.

These *life members* are still active members and are counted for determining representation in the AMA House of Delegates.

The AMA membership rules provide that an active member may be excused from the payment of dues when it is deemed advisable by the Board of Trustees, provided that he is partially or wholly excused from the payment of dues by his component society and constituent association.

The opinion, therefore, seems unanimous that a society member who reaches three score years and ten and has been a member for forty years should receive free membership for life in county, state and national medical organizations.

AN EDITOR'S WISH

The following editorial is reprinted verbatim from the *New England Journal of Medicine* (December 20, 1951), as it expresses exactly our wishes.

> It has been an old custom with the *Journal* at this season to prepare and release some sort of editorial statement concerning Christmas. This has usually been in the nature of a brief comment on the advantages of good will among men and the desirability of peace on earth. Depending partly on the world conditions that happened to prevail at the moment and partly on the state of mind of the particular editor who was responsible for the release, the tone of the editorial has been *(a)* hopeful or *(b)* unhopeful. There is no indication that these efforts, regardless of their literary merit, have as yet made any impression on the global situation.
>
> This year the editors have decided to withhold their annual attempt to promote the goodwill industry and to give a try, instead, to the equally prevalent custom of presenting their own Christmas list and to see what comes of it.
>
> Here is what the editors would like for Christmas—and, indeed, for the whole new year.
>
> They would like to receive a reasonable number of topflight new manuscripts—perhaps 250—from which they could make their choice, containing from 800 to 4,000 words each, decently typed with double or triple spacing (including the case reports, footnotes and references) on a typewriter with a fresh ribbon. They would like to have the references limited to those of real significance, following accurately the style of the *Cumulative Quarterly Index Medicus.* (The only impression that inflated "bibliographies" make is a bad one.)
>
> Needless to say, perhaps, any paper that is fit to be published is written in as good English as the author can muster and is then rewritten at least twice, with a number of words discarded at each writing; for anything that is worth saying at all is usually said twice

Medical Economics

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

BRITAIN "IMPROVES" HEALTH SERVICE PLAN

The British Health Service, after a struggling and expensive existence of supplying many people with new teeth and new wigs, has recently submitted itself to a change which has recognized the qualities of "human necessities and human frailties."

An editorial in a recent issue of the Toronto, Canada, *Globe and Mail;* takes a logical point of view, stating:

> "In Britain there is all-party agreement on the principle of national health insurance. Debate now centres on the question how to make it work fairly and reasonably. The Conservative Government's decision that small fees will henceforth be charged for various kinds of medical and dental service does not rescind a Socialist policy; nor is it merely a way to save money for the Treasury. *It will improve the health scheme by a recognition of both human necessities and human frailties.*"

The idea that ill health and illness are only hard luck and that the individual in a good society should not have to pay their penalty, was manifested to the fullest extent in the Socialist Government's 1948 health law. Anybody could get, free of charge, whatever medical, surgical, dental and hospital care he needed simply by paying a weekly contribution to a national fund. This, however, has proved impractical. The *Globe and Mail* points out:

> "This is a fine plan on paper but even the Socialists were compelled to admit that it didn't work in practice. Human nature, it was found, does not stand up to the enticements of a health service that is 100 per cent gratis, not even British human nature which is notable for common sense and moderation. When medical advice is to be had for the asking and everything from headache pills to toupees is buckshee, people feel ill oftener than they should and fill up their medicine cabinets with all sorts of superfluous bottles and appliances."

Danger of Decline

Not only did the British health service cost over one-third more than the original estimate for a year, but, according to the paper, "there was a decline or at least the danger of a decline, in the standards of professional health service because people with nothing wrong with them were crowding into doctors' offices, wasting their time and obliging them to scamp the attention they could give each patient."

The changes in the plan are only a modifying policy. There is to be a maximum charge for dental services of one pound, with the state paying the remainder if it is larger, and the patient paying the entire amount if it is smaller. There will be slightly higher charges for private hospital beds, surgical aids and medicines. "These revisions do not alter the basis or framework of health insurance," the Canadian paper states. "They merely make the structure less topheavy."

The editorial concludes that the British government:

> ". . . is saying in effect that illness is not entirely hard luck. The individual has a duty to look after his teeth and his general health. If he fails, he ought to pay at least a small fraction of the expense of putting him right in addition to the regular contribution which only partly covers the cost of insuring him. . . . There is an advance here toward realism as well as toward justice and economy."

NATIONAL FIRM PRAISES DOCTORS

A two-page advertisement for a national automotive concern, seen lately in many national magazines, pays tribute to medical progress by a comparison of transportation facilities in the early 1900's and now.

Under a picture of a doctor in his horse-drawn buggy, is this statement:

> "The oldtime doctor fought disease and ignorance and dirt—and spent his nights on the country roads, going lickety-split to the patient, and at a drowsy jog

on the way home." Over a picture of today's doctor arriving in a car at the patient's home, is this statement: "Today's patient can be reached swiftly: the American Road brings the doctor to every door in the land. To be an American is to be within reach of the miracles of medicine."

Bringing in the development of the automobile as a great step in aiding American progress, the advertisement traces statistics on automobile ownership and their relation to health progress in America:

> "Today nearly every one of the 200,000 U. S. physicians uses the automobile and thousands of visiting nurses depend on the car. More than 28,000 motor ambulances stand ready to bring patients to our 6,430 hospitals.
>
> "There are 50 per cent more hospitals now than at the turn of the century, and hospital-bed capacity has more than tripled. Almost every automobile is an ambulance at some time, it seems, taking the doctor to you, or you to the doctor."

PR PROGRAM GAINS MOMENTUM

The stepped-up public relations program of the American Medical Association, as described by Leo E. Brown, director of the Department of Public Relations, "logically divides itself into two phases: internal and external. The internal phase is concerned primarily with relationships between the AMA and other medical organizations and between the AMA and the individual physician. The external phase is concerned primarily with the attitudes of the public toward the medical profession, either as individuals or as groups."

Speaking at the December public relations conference in Los Angeles, Mr. Brown outlined the following general public relations objectives for the coming year:

> "1. To gain public support for the American Medical Association by informing the people of the policies, objectives, and accomplishments of the Association.
>
> "2. To strengthen the support of members for the American Medical Association by making known to them the objectives, accomplishments, and services of their Association.
>
> "3. To improve physician-patient relationships by encouraging the physician to administer his services promptly, efficiently, and courteously, with understanding of the patient as an individual, and in line with the first sentence of the Principles of Medical Ethics: 'The prime object of the medical profession is to render service to humanity . . .'
>
> "4. To encourage our constituent state and county medical societies similarly to continue and expand their own public relations activities, thereby cementing physician-patient and community relationships at the grass roots.
>
> "5. To work toward the solving of the economic problems arising from the cost of illness."

Mr. Brown pledged the department's constant work to attain these goals through the many public relations media at its disposal. He listed the use of weekly news releases, new and improved brochures, reprints from popular magazines, publicity service for the many councils, bureaus and committees of the organization, radio, television, and film activities, an expanded information service to magazine editors and free lance writers. Also, the department proposed to "(1) continue the promotion of impartial 'grievance committees'; (2) continue the promotion of twenty-four-hour emergency call services; (3) to encourage the physicians to police their own ranks and take disciplinary action against members guilty of unprofessional and unethical conduct; (4) become civic-minded, active in worthy community affairs, and publicly stand for high morals in government; and (5) encourage our state and county medical societies to support and promote other Association activities, such as school health, civil defense, and rural health, as an integral part of their own PR program."

Praises State Work

Concluding his remarks, Mr. Brown put in a word of praise for the excellent work done by state and county medical societies in this field:

> "The co-operation we have received from our state and county medical societies has been excellent, and I want you to know it is appreciated. You have joined forces with us, and I trust we can continue to pull together.
>
> "We have made mistakes during the past year—we will make some during the coming year. There are many things to be done, goals to be achieved, but we are moving ahead and, with your help, will continue to progress."

COUNTY SOCIETY STARTS EFFECTIVE PLAN

In answer to the proponents of socialized medicine who say that there are hundreds of individuals going without medical care who would be guaranteed it under their plan, one county medical society has countered with its own guarantee: to supply medical care for all who cannot afford it. The original vote of the medical society obligates every member to accept a reasonable number of cases.

When the plan was first inaugurated, skeptics were quick to say that it was a publicity gimmick and that it was not on the level. But such is not the case, according to the society's executive secretary, for the plan was genuine and set in a firm foundation. The offer is still good after five years and many other counties have tried and found this same type of program successful.

The proof came in the actual working out of the program. In six months after the first advertisement announcing the plan, there had been only fifty-nine calls altogether. The executive secretary stated:

> "When we come face to face with some of the 'do-gooders' who tell us there are dozens of persons in this town going without medical care, we are able to say, 'That is interesting to us; would you get us the name of the first lady you would like to have taken care of in the group you are talking about?' In one instance, we needled a small group for three weeks trying to get the name of the first person they were talking about. It is surprising but very pleasing to see the reactions when we follow up on the false claim that there are hundreds of persons going without care. At the same time, it is a great source of satisfaction when you find someone who really needs it, who is going without it, simply because he just does not know where or how to find the physician who will be willing to take care of him without charge."

Summing up the obvious public relations value of such a program, he said:

> "Our doctors are not operating the jackpot I referred to earlier. They are just being good doctors and good neighbors. We believe that medical public relations are better in those local counties where the guaranteed medical-care-for-all plan exists, because in those counties the ethical physician, who will abide by the solemn promise never to turn his back on human suffering because he might not get paid, is not a mythical character. He is not someone whose name can't be remembered in times of sickness or apparent need. He is easy to find, because he is the total local medical profession. He is the county medical society."

It is rare, indeed, to see an American child with a hunchback as a result of infection with bovine tuberculosis. Virtual eradication of this disease in cattle has nearly eliminated one very important source of infection in children and in adults who might be exposed to the infection through direct contact or consumption of milk from tuberculous cattle.—C. H. PALS, D.V.M., Am. J. Pub. Health, September, 1951.

AN EDITOR'S WISH

(Continued from Page 236)

as well in half the number of words. Its tables and charts are few and simple and properly captioned. In its final state it is crystal clear and informative and meets some need other than that of the author for publicity.

After all, the only really valid reason for writing a scientific medical article is to present the results of useful investigation or seasoned experience, thus adding to the sum of medical knowledge, or to bring together and correlate existing knowledge in order to make it more easily available. Only occasionally is a single case worth reporting, to remind a journal's readers of the existence of some condition that may cause diagnostic confusion or to add to the knowledge of its treatment; it should be reported with the utmost brevity. A case report should always point a moral, whether or not it may adorn a tale.

The editors would like to find in their stockings the promise of a series of inspired and carefully worded editorials on a variety of pertinent subjects and a salty but amiable correspondence suitable for publication. They would be pleased with a strict observance of deadlines on all promised material.

Given these things, a circulation that continues to expand, and a growing list of contented advertisers, they will believe that there really is a Santa Claus!

Minnesota Academy of Medicine

Meeting of May 9, 1951

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, May 9, 1951. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 p.m. by the President, Dr. W. H. Hengstler.

There were forty-eight members and eight guests present.

Minutes of the April meeting were read by Dr. Charles Rea, in the absence of the secretary. They were approved as read.

Dr. A. E. Benjamin read the following Memorial to Dr. H. B. Sweetser, Sr., and a motion was carried that it be spread on the minutes and a copy sent to the family.

HORATIO B. SWEETSER

1861-1950

Dr. Horatio B. Sweetser, of 2509 Pillsbury Avenue, Minneapolis, died May 23, 1950, at the age of eighty-eight. He was born in Brooklyn, New York, July 13, 1861. Doctor Sweetser was graduated from St. John's College in the city of his birth in 1877, receiving his medical degree from the College of Physicians and Surgeons in New York City in 1885. A period of internship was served in St. Francis Hospital of New York from 1885 to 1886. Doctor Sweetser engaged briefly in the practice of medicine in New York before journeying to Minneapolis in 1887.

Doctor Sweetser served as professor of anatomy and surgery at Hamline University in Saint Paul and in a similar capacity at the University of Minnesota Medical School following a merger of these two medical departments.

Doctor Sweetser was a charter member of St. Mary's Hospital of Minneapolis. His affiliation with this hospital coincided with his arrival in this community in 1887, and for many years he ably served as Chief of Staff at St. Mary's.

Doctor Sweetser was a member of the American College of Surgeons, the Western Surgical Association, the Minnesota Academy of Medicine, over which he presided in 1919, the Minneapolis Surgical Society of which he was president in 1927, the Hennepin County Medical Society, whose activities he directed in 1899-1900, the Minnesota State Medical Association and the American Medical Association.

Doctor Sweetser was a member of Phi Rho Sigma, undergraduate medical fraternity, the Minneapolis Athletic Club, the Minneapolis Automobile Club, and the Bloomington Golf Club.

The family name will continue to be ably associated with medicine through the two sons who survive him, Theodore H. Sweetser, M.D., and Horatio B. Sweetser, Jr., M.D. There are two daughters, Mrs. Frank Preston of Minneapolis, and Mrs. Elizabeth Albrecht, of Belle Plaine. Doctor Sweetser's wife preceded him in death in 1936.

Doctor Sweetser was a dynamic person. He was a good clinician and surgeon, a keen observer, and a conscientious practitioner. He had the confidence of his patients and the esteem of his confreres.

We all admired his analytical mind and deep convictions. He was a good debater and loved to match his wits on any debatable question with his colleagues. His arguments carried weight in committee and general meetings of the organizations to which he belonged. He was a faithful attendant at the meetings of the Academy.

His patients were well served by his skills and accomplishments.

Dr. E. T. Evans read the following Memorial to Dr. Vernon L. Hart.

VERNON L. HART

1898-1950

Vernon L. Hart was born on October 24, 1898, in Huron, Ohio. He received his medical education at the University of Michigan where he was graduated in 1924. From 1924 to 1932, he served on the surgery and orthopedic services at Ann Arbor. He served as Head of the Department of Orthopedics prior to establishing private practice in Dayton, Ohio, from 1932 to 1933.

In the fall of 1933, he established residence in Minneapolis, taking over the practice of the late Dr. Emil Geist, maintaining that high quality of practice initiated by Doctor Geist.

He was a Fellow of the American College of Surgeons and a Diplomate of the American Board of Orthopedic Surgeons. He was a Fellow of the American Academy of Orthopedic Surgeons and a member of the Clinical Orthopedic Society. He was, of course, a member of the American Medical Association and of the State and County Medical Societies. We remember him best as a member of this Academy.

He enjoyed an enviable reputation based upon meticulous attention to detail and a keen appreciation of the fact orthopedic disabilities are frequently major disasters in the life of the patient. Because of this he was beloved by his patients and respected by his colleagues. He was a member of the active staffs of Swedish, St. Barnabas, Abbott and St. Mary's Hospitals. He remained active in teaching in association with the University Hospital group.

I have mentioned his attention to detail. He carried this into every effort of his professional career and it was reflected in numerous contributions to orthopedic literature in which he insisted upon carrying out a logical and orderly procedure. He will long be remembered for his classical contribution to early diagnosis and evaluation of dysplasia of the hip and its relation to congenital dislocation of the hip.

He entered Service in World War II as a Major of the Army Medical Corps on May 12, 1941, and served with distinction until his separation from Service on April 1, 1946, with the rank of Lieutenant Colonel, at which time he was Orthopedic Consultant to the 5th Army Area.

He was a member of the National Research Council and in 1948 he served as a civilian consultant to the Surgeon General United States Army, inspecting the American Zone in Germany.

He had a host of friends, professional and non-professional, to whom his untimely death on July 12, 1950, came as a great shock.

The community, and the orthopedic profession especially, joins in tribute to a real gentleman, a fine teacher, and a talented surgeon. It extends its sympathy to his wife, Ruth, and daughter Louisa K., who, in their bereavement, are sustained with pride in his achievements.

A motion was carried that this memorial be spread on the minutes of the Academy and a copy sent to Doctor Hart's family.

The chairman of the Program Committee discussed programs for the future, for consideration by the members prior to discussion at a future meeting.

The scientific program followed.

PLASTIC OPERATIONS FOR HYDRONEPHROSIS

FREDERIC E. B. FOLEY, M.D.
Saint Paul, Minnesota

(This paper will appear in a later issue of MINNESOTA MEDICINE)

ROENTGENOLOGIC DIAGNOSIS OF BENIGN GASTRIC ULCER

A Preliminary Report of 133 Cases*

C. J. CORRIGAN, M.D. and HAROLD O. PETERSON, M.D.

(Abstract of presentation with numerous lantern slides by Dr. Peterson)

What is the incidence of malignancy in gastric ulcers which appear benign roentgenologically? That is the question which prompted the present study. The impression gained from the literature is that 10 to 30 per cent of gastric ulcers are malignant depending on their location. Ulcers on the greater curvature are considered to be 100 per cent malignant. There is one serious criticism of all the statistics of this type, namely, that they include only operated cases or cases studied postmortem. This represents a select group and does not include all the people who have gastric ulcers and never come to surgery or autopsy. A group which would include all gastric ulcers with or without surgical treatment would obviously be a more accurate representation. Unfortunately such a group would lack histological verification in a high percentage and one would have to depend on the clinical and roentgenological course for the final diagnosis.

Because we could not recall a single case of benign gastric ulcer being later proved to be malignant we decided to make an accurate investigation of our cases. All the patients who had had a diagnosis of benign gastric ulcer roentgenologically during the past 11 years were included in this study. To this group were added all the cases in which a benign ulcer was found in the surgical or autopsy specimen even though the roentgen diagnosis had been indeterminate or suggested carcinoma. All of the patients had been examined either at the Miller Hospital in Saint Paul or the Interstate Clinic in Red Wing, Minnesota.

Over an eleven-year period, 133 cases of gastric ulcer were collected and an attempt was made to obtain follow-up information on all of them. Seven of these were diagnosed roentgenologically as being carcinoma or probable carcinoma and all proved to be benign histologically. The remaining one hundred and twenty-six were called benign roentgenologically. Fourteen of these had histologic studies and three carcinomas were found. In one of these three cases postmortem studies cast some doubt as to whether the carcinoma actually arose in the stomach. The second case was a huge carcinoma of the stomach and should have been diagnosed as such roentgenologically and is therefore an error in judgment which should not have been made. The third carcinoma was superficial in type involving only the mucosa in a small zone around the ulcer with no tumor cells in the ulcer itself. Hebbel believes these cases are primary superficial carcinomas of the stomach with secondary ulceration. They cannot be distinguished roentgenologically from a benign ulcer.

Five other cases were operated upon but no specimen obtained. Four of the five had gastro-enterosto-

---

*Since this presentation, fifteen more cases have been added to the original 118 and have been included in the summary to bring the total to 133 cases.

TABLE I.
CASES WITH LESS THAN 1-YEAR FOLLOW-UP

Healed by X-ray Examination	15
Not healed	8
Improved	9
No follow-up	6
Dead (1 Ht. disease; 1 hemorrhage from BGU)	2
Total	40

TABLE II.
CASES WITH MORE THAN 1-YEAR FOLLOW-UP

Years Follow-up	Well	Not Well	Dead	Total
1-2	11		1	12
2-3	9		1	10
3-4	6		1	7
4-5	9		1	10

6-7	4	1		5
7-8	1		1	2
8-9	4		1	5
9-10	1			1
10-	4			4
Total	57	3	7	67

mies and the fifth case required surgery to close a perforation. To summarize the twenty-six surgical and autopsy cases, nineteen had gastric resections, four gastroenterostomies, one closure of perforation, one exploration followed by autopsy, and one autopsy after terminal hemorrhage.

The remaining 107 cases had a clinical follow-up with or without repeated roentgen examinations as shown in Tables I and II.

There were thirteen deaths in the entire group, of which six were not related to the gastric ulcer and seven were related. Of the seven deaths related to the ulcer three occurred in the immediate postoperative period and a fourth postoperative death followed a third operation necessitated by complications from the gastric resection. Two medical deaths followed gastric hemorrhage and one patient died as a result of obstruction from an hour-glass stomach at the age of eighty-six.

The ulcers were located as follows: forty-three in the prepyloric area all benign; eighty-eight on the lesser curvature above the prepyloric area with three carcinomas; and two on the greater curvature both benign. The size of the ulcer had no significant relationship to the incidence of malignancy.

Only thirty cases had gastric analysis and many of these were done with alcohol and not histamine. Most of these had free hydrocholric acid values of less than 30° and some were achlorhydric.

Conclusions

1. Three known carcinomas were found in 133 cases of gastric ulcer.

2. The size and location of the gastric ulcer is of no diagnostic aid in the differentiation of benign or malignant ulcers.

3. Achlorhydria is of no value in the differential diagnosis of benign gastric ulcers.

4. Superficial carcinoma of the stomach with ulceration cannot be distinguished from benign gastric ulcers. This is a very rare type of ulcer.

5. No case of gastric ulcer should be dismissed until the ulcer has either healed and remains healed for a reasonable time or a resection has been done.

Discussion

Dr. L. G. Rigler, University of Minnesota. This is a very interesting paper to me because we have gone through a great many evaluations on this subject. A great many years ago, L. G. Cole said he thought there were many cases in which he could establish a diagnosis. He thought that in about 90 per cent one could say with great certainty that an ulcer is benign or malignant, and in 10 per cent no distinction could be made. I used to think that, but in later years I have learned from sad experiences that this is an optimistic view. I think we at the University Hospital have a rather unsatisfactory experience as we don't see the ordinary garden type of case. I don't think I would have disagreed with any but one of those Dr. Peterson presented. The cases we see are much more irregular and I suppose that is natural. We have a conference with the surgeons each week, and all the material of the week is then exhibited; we then try to make a statement as to what it is. We have had the experience of having the surgical pathologist and the surgeon with the specimen in front of them still uncertain; sometimes they are 100 per cent wrong as to what it is. It certainly is true that in a few cases, a small very benign looking ulcer proves to be a carcinoma. The unfortunate thing is that one is not always sure as to which we are dealing with. I do think one has to bear in mind the kind of material one is dealing with—whether it is the ordinary material that comes into a clinic, for instance, or those we see which give a lot more trouble.

Dr. O. H. Wangensteen, University of Minnesota: This recital of Dr. Peterson's experience has been impressive. However, I am inclined to agree with Dr. Rigler that when Dr. Peterson has all the reports in on his cases, he may find his present judgment tempered by a more complete evaluation of his own experience. There are no Delphic Oracles in Medicine. Even the pathologist, with the excised lesion in his mind, finds it necessary quite often to await the verdict of the microscope before giving his opinion with reference to the important question of whether an ulcerative gastric lesion is a benign ulcer or a cancer. And every now and then, the pathologist finds it necessary to reverse himself. The circumstances are usually these. A large craterous gastric ulcer has failed to heal completely under medical management. The pathologist, when he has examined many sections cut from several areas in the ulcer gives the verdict of a benign ulcer. A year or two goes by, and the patient feels well. Then presently, his health begins to fail. He comes back looking like a scarecrow. His neighbors know that the patient had an operation upon his stomach. They know now that he had cancer. They believe, the patient has a recurrence. Moreover, they are probably right. The surgeon has the pathologist look at the patient. The gross specimen is resurrected; many more sections are cut. And the cancer is found. I have had this experience several times. It concerns almost invariably a large ulcer. Certainly not every large ulcer is a cancer. Nevertheless, such large ulcers should be suspect.

Determination of gastric acidity is important. The incidence of achlorhydria or hypochlorhydria in gastric cancer is frequent. To be certain, there are patients with gastric cancer who have free HCl in the gastric contents; however, such patients are in the minority. It is amazing how frequently physicians omit performance of gastric aspiration to determine gastric acidity. In the Cancer Detection Center, asymptomatic patients, who are found to be achlorhydric to histamine, are subjected to x-ray examinations of their stomachs. During the past year, I have seen three achlorhydric patients, who, at operation were found to have gastric cancer. All three had been treated as having peptic ulcer on the basis of x-ray evidence, without having had the gastric contents assayed for free HCl. One of them had been gatroscoped several times!

As Dr. Rigler intimated, Cole of New York City was in part responsible for the veering about in attitude toward a more conservative treatment of gastric ulcer. Here in the mid-west, Wilson, MacCarthy and Carman of the Mayo Clinic, as well as William J. Mayo and C. H. Mayo were supporting the thesis that a benign gastric ulcer may become transformed into a cancer. Some of that discussion generated more heat than light. Certainly, it should be said now, that whereas the danger of malignant transformation probably was not as great as some of the men of the Mayo Clinic of that day believed it to be, nevertheless, when the problem is reviewed in the aggregate, bearing in mind all the practical implications, the men of the Mayo Clinic held, for that day, what today might be called a very modern view.

All the evidence points directly toward the necessity of viewing the persistent gastric defect with suspicion. We would all agree with Dr. Peterson that the garden-variety of ulcer occurring typically on the lesser curvature just above the infundibulum which disappears completely under medical management—such an ulcer need not be suspect for cancer. It may come back nevertheless in the very same area after the elapse of some months, with reassertion of clinical symptoms. In thirteen patients in our Clinic with x-ray defects on the lesser curvature, which healed out completely, adjudged from disappearance of a defect detectable by x-ray examination, gastric resection was carried out anyway. One of the thirteen had a cancer. In only one of the remaining twelve was the defect completely covered with epithelium. In all instances, peninsulas of epithelium went out from the edges of the ulcer, but in most of the instances, these bridges of epithelium did not cover the defect completely. I regard this microscopic study of apparently healed gastric ulcers as important. These observations of my surgical colleagues, Drs. Henri, Sanchez, Lyle Tongen and Stanley Friesen have not been published yet. They do indicate however why the ulcer frequently comes back in the very same spot. The ulcer probably failed to heal completely in the first instance leaving an area unprotected by normal gastric epithelium.

The important bits of evidence however which confront anyone who takes the point of view with reference to diagnostic accuracy in differentiating whether a persistent gastric defect is a benign ulcer or a cancer by *any* means other than microscopic verification are the reported findings of pathologists upon the histology of allegedly benign gastric ulcers removed by surgeons. In the experience of the Lahey Clinic (1948) this figure is 18 per cent; at the Massachusetts General Hospital it is 14 per cent; for our own Clinic it is a little more than 10 per cent. If one affects the role of a prophet in this difficult task of deciding, in certain persistent defects, whether a lesion is benign or malignant, his prophecies may boomerang upon him.

Whereas, striving for perfection is a laudable, if unattainable, objective in many spheres of our activity, we may justify the censure of our colleagues or society if in striving for such perfection, we assume risks for our patients which experience suggests we are not warranted in taking. There are times when we must ask ourselves: What is the important consideration here? Is there a good chance that I may be wrong? Yes, we are all human and very fallible. Long years ago, my colleague, Dr. Rigler began including in his report in questionable situations the following statement: "The presence of cancer cannot be excluded." That statement serves to alert the clinician to the potential serious import of the condition. It has had, in most instances, a very salutary effect upon the physician. It puts the responsibility where it belongs. What if the roentgenologist said I believe the lesion is benign and advise a period of conservative management. Why should he assume this responsibility? Here striving for academic perfection is a disservice to the patient and those responsible for his care. I feel that Dr. Rigler should be commended for his frankness and his sincerity. That view is synonymous with alertness in the early detection of gastric cancer.

Dr. L. A. Nash, Saint Paul (by invitation): Since I am a guest of the Society and also an associate of the speaker, I hesitate to raise my voice. I do not believe that on radiological criteria alone, most of us can be as sure of ourselves in this matter of seperating cancer ulcers from benign ones as Dr. Peterson appears to be. As a radiologist, I have been accused of playing into the hands of the surgeons in favoring early resection of gastric ulcers, basing my thinking on the idea that cancer must be removed early to be cured. The errors we make are greater in each group of cases than the current operative mortality. However, with improved apparatus and increased knowledge, there is growing evidence that the differentiation can be made more often and I think Dr. Peterson has indicated that tonight. On the other hand, I must agree with Dr. Wangensteen and will wait with interest a second hundred cases to be reported by Dr. Peterson to see if the diagnostic error does not approach the "standard error of diagnosis" occurring in other documented analyses.

Dr. Peterson, in closing: I wish to thank the discussors for their frank remarks. I expected considerable criticism of this paper since it presents a viewpoint directly opposite to the prevailing opinion of most surgeons and many radiologists. Before looking up our cases of gastric ulcer, I had the impression there would be very few, if any, ulcers which were diagnosed as benign that proved to be malignant. Until two weeks ago we had not uncovered a single proven carcinoma; but, in reviewing the earliest patients who were examined and operated on ten years ago, we discovered two malignancies. This low incidence of malignancy (two in 118 cases) substantiates my impression. I believe the chief reason for the scarcity of carcinoma in this group of ulcers is the fact that these cases represent the typical clinical type of gastric ulcer observed by the average physician in private practice. The group is not limited to people who have had resections, especially in the larger centers, but include every one with an ulcer demonstrable on roentgen examination whom we have studied during the last ten-year period. The lack of histologic proof on most of these cases can be criticized but

Minneapolis Surgical Society

Meeting of May 3, 1951

The President, HARVEY NELSON, M.D., in the Chair

SURGERY OF TUMORS AND HYPERFUNCTIONING STATES OF THE ADRENAL GLANDS

DAVID STATE, M.D.
Minneapolis, Minnesota

The striking clinical picture which accompanies derangements of the adrenal glands has made these conditions a most interesting subject for study. The purpose of this paper is to present the examples of the more common derangements of the adrenal glands seen and treated at the University Hospitals from 1941 to 1951.

Embryology

The medulla is derived from the embryonic neural crest and thus has a common origin with the sympathetic ganglia. The cells are further differentiated into nerve cells and chromaffin cells, the latter taking a characteristic brown color with chromic acid stain.

The cortex arises from the celomic epithelium near the origin of the germal epithelium of the sex glands.

The adrenal is largest at birth with the major portion of the gland being composed of adrenal cortex. The latter is divided into large inner androgenic or "X" zone and a thin outer layer of cortical cells similar to that observed in later life. The reduction in size of the adrenal cortex after birth is due to the rapid degeneration of the "X" zone and the true cortex which is left behind, continues to grow and develop. Adrenal cortical cells grow continuously from without in, that is, cells arise from the spindle shaped cells under the fibrous capsule and pass inward to form the three zones; the zona glomerulosa, the zona fasiculata and zona reticularis.

Physiology

Adrenal Medulla.—Adrenalin is apparently formed from the chromaffin cells. The release of adrenalin is largely an emergency function and as is well known, causes vascular constriction, dilatation of the coronaries, increased contractility of the heart, etc. The adrenal medulla, however, is not absolutely essential for life.

Adrenal Cortex.—Hormones elaborated here manifest the following distinct metabolic activity: (1) maintenance of the electrolyte and water balance, (2) influence on carbohydrate metabolism and (3) augmentation of protein anabolism.

The importance of the adrenal cortex is related to various stresses such as burns, trauma, fatigue, etc., has been recently emphasized by Selye. How the adrenal cortex helps in homeostasis is not entirely clear. The cortex is essential for life.

Diseases of the Adrenal Glands

Tumors of the Adrenal Medulla

Neuroblastoma.—These tumors arise from the nerve cells of the medulla and depending upon the stage of development of the cells at the time of neoplasm formation, the tumor has a varied malignancy. The neuroblastoma is by far the most common and it is the most common neoplasm of the abdominal cavity in children under the age of four. Clinically these tumors are small and encapsulated early but they are soon capable of invasion of the adjacent organs such as, kidney, mesentery, vertebra, pancreas, etc. Metastases also occur readily both by lymphatic and blood streams with the lung, liver, brain and skeletal system most often being involved. The patient most frequently complains of vague symptoms such as, weakness, easy fatigability, loss of appetite and pain in the back. Examination reveals, usually, an enlarged abdominal mass. Treatment, ideally consists of excision of the tumor but because of the rapid growth this is rarely possible. Roentgen therapy should be given even though metastases may be present. Farber has seven patients out of thirty-two who have survived two or more years following either complete surgical removal or x-ray therapy. Two of these patients had liver metastases.

Pheochromocytoma.—This neoplasm arises from the chromaffin cells of the adrenal medulla and produces symptoms characteristic of those due to release of adrenalin into the blood stream. One, therefore, sees arterial hypertension, tachycardia, nausea, vomiting and sweating. Green has shown that symptoms may be chronic or persistent as well as intermittent. Diagnosis may be assured by the use of a sympatholytic drug such as, dibenamine or benzodiazine which cause a fall in blood pressure if the hypertension is due to pheochromocytoma.

From a surgical point of view, the major problems in handling cases of pheochromocytoma are those related

---

Inaugural report presented before the Minneapolis Surgical Society, May 3, 1951. Studies herein reported were supported by grants from (1) Graduate School, University of Minnesota, (2) Malignant Disease Research Fund, and (3) Flora L. Rosenblatt Fund.

to the marked elevation of blood pressure associated with manipulation of the tumor during operation and the percipitous fall following removal of the tumor. In order to combat the former, a short acting drug such as benzodiazine or amyl nitrate by inhalation may be used. To counteract the marked fall in blood pressure which occurs after removal of tumor the following points are important. (1) Epinephrine in 1/100,000 solution, whole blood, and adrenal cortical extract should be available before operation is started. An "intravenous" with a large bore (No. 15) needle should be inserted before operation is started. (2) Wide exposure of the adrenal should be obtained so that manipulation is reduced to a minimum and the vascular supply to the gland is made available for clamping. The transabodominal approach is excellent in this regard. (3) Before removal of the tumor, the pedicle should be clamped and released repeatedly with the period of occlusion gradually increased until the pressure remains stable after a period of ten minutes of pedicle clamping. (4) If a percipitous drop of blood pressure occurs the epinephrine solution and whole blood should be given quickly and in sufficient quantities to bring back the blood pressure to normal levels. Adrenal cortical extract in doses of 10 cc. intravenously should also be given. Postoperatively, the patient should be watched carefully for delayed drops of blood pressure.

The mortality rate continues, however, to be high and the longer the duration of the disease the higher the mortality. In children, to date, the death rate in the operation has been very high, about 58 per cent.

Diseases of the Adrenal Cortex

Hyperadrenocorticism.—Nearly all cases may be divided on the basis of their predominating metabolic manifestations into two groups: (1) Adrenogenital syndrome and (2) Cushing's syndrome.

1. *Adrenogenital Syndrome*

(a) *Congenital adrenal hyperplasia in the female.*—This is the most common adrenal disorder encountered in children. At birth these children have an enlarged clitoris which is bound ventrally by a fibrous cord. The labia majora are hypertrophied while the labia minora are underdeveloped. There is a single urogenital sinus which gives a common opening for the urethra as well as the vagina. Uterus, ovaries and Fallopian tubes are present. From birth on there is rapid somatic growth, sexual hair growth, muscular development and epiphysial ossification. The voice becomes deep and the excretion of 17 ketosteroids is always increased in relation to the patient's age.

Pathology.—Both adrenals are usually enlarged to about one and one-half to three times normal size. Occasionally the hyperplasia appears to be unilateral. Microscopically the glands are composed largely of polyhedral granular cells similar to those of the foetal androgenic or "X" zone.

Differential diagnosis.—The condition must be distinguished from (1) intersexuality or hermaphrodism, (2) postnatal virilization and (3) sexual precocity of the iso-sexual type. Differentiation from these conditions is made upon the fact that from birth on the clitoris is enlarged and there is urogenital sinus for a common opening for urethra and vagina. These other conditions that may simulate pseudohermaphroditism of the female but they do not have a urogenital sinus.

Treatment.—This is a complex and difficult task. Unfortunately, the removal of one adrenal or portions of both adrenal glands has resulted in no significant change in the clinical course. Recently Wilkins has called attention to the fact that cortisone may possibly repress excessive androgenic function and this is worthy of trial to prevent progressive virilization in selective cases. If the diagnosis is made early in childhood it may be well to raise the child as a girl and to this end the the clitoris may be amputated. At the time of puberty attempts at increasing femininity may be made by using estrogenic hormones. Where the patient has been raised as a boy it is best to pursue this path for at puberty there is excessive androgenic activity. The chordee may be corrected and plastic procedures to form a penile urethra may be carried out.

(b) *Adrenal hyperplasia in males (macrogenitosomia praecox).*—In this condition the penis is usually enlarged at birth but this may not occur until the child has reached one and one-half to two years of age. The voice becomes deep and other evidences of secondary sex characteristics such as, hair on the pubes and in the axillae and on the face, also develop early. The excretion of 17 keto-steroids is markedly increased but the testes characteristically remain small and immature. This latter point is of extreme importance in the differential diagnosis of this condition from other endocrine disturbances which may give a similar clinical picture. Although somatic growth is rapid at first, epiphyseal fusion occurs early so that by the tenth year growth is completed and the patient remains a short adult with broad shoulders and powerful muscles.

Treatment.—There is no effective way of inhibiting the excessive production of adrenal androgens but in the male the outlook is much happier than in the female with congenital hyperplasia because the patient ends up with masculine features although he is short and stocky. It may also be possible to delay early epiphyseal fusion in certain cases by the use of cortisone. As in the female patient, special attention must be paid to the psychotherapy of the individual so that he can be eased into his environment with the greatest facility.

(c) *Virilizing tumors in females.*—Excessive androgenic activity of the tumor is characterized by the rapid growth of the clitoris, appearance of pubic and axillary hair, deepening of the voice and the onset of seborrhea and acne. Unlike the patient with congenital hyperplasia of the adrenal, however, the external genitalia are normally formed. The 17 keto-steroid excretion is increased and the beta faction may also be increased. These neoplasms are prone to be malignant and may metastasize early to lung or bone or to the liver. Treatment consists of removal of the adrenal tumor. If therapy is successful there is reversion of the patient to a normal female appearance. In addition the excretion of 17 keto-steroids is repressed to normal levels and remain so if there are no evidences of recurrences.

(2) *Cushing's Syndrome.*—This syndrome is characterized by increasing obesity of the "buffalo" variety, that is, deposition of fat about the shoulders and face, weakness, purple striae of the abdomen, increased capillary fragility, osteoporosis, hypertension, virilization of the female, diabetic blood sugar curve, increase in serum sodium and decrease in serum potassium. There is an increase in the urinary excretion of 11 oxysteroids and 17 keto-steroids. In children there are evidences of sexual precocity but not as marked as in congenital hyperplasia.

Pathogenesis.—Thompson and Eisenhardt studied ninety-eight cases that came to autopsy and showed that basophil adenoma of the pituitary is found in approximately 60 per cent and adrenal tumors in 22 per cent. It is generally agreed that the symptoms of Cushing's syndrome with or without pituitary tumors are due to excessive production of the hormones of the adrenal cortex. Wilkins states that all cases of Cushing's syndrome beginning before the age of eleven years are due to adrenal tumors.

Treatment.—When the Cushing's syndrome is due to adrenal tumor its removal results in reversion to normal on the part of the patient. When adrenal hyperplasia occurs the treatment of Cushing's syndrome is usually unsatisfactory. Radiation of the pituitary and the use of testosterone and estrogens to combat osteoporosis has been advocated. From a surgical point of view, removal of one adrenal gland usually results in little change though we have encountered one patient who had excellent results following unilateral adrenalectomy and the group at the Mayo Clinic have performed bilateral subtotal adrenalectomy in three patients with appreciable improvement.

General Comments Concerning Localization and Removal of Adrenal Cortical Tumors

Localization may be difficult when the tumor is not palpable. A flat plate of the abdomen may show calcification and planograms are helpful and should be done in all cases. Pyelograms may show abnormal displacement of one kidney by an overlying mass. Cahill advocated perirenal air insuflation but this is not without danger and results are frequently inconclusive. Whenever clinical and laboratory findings are sufficient to suggest an adrenal tumor, provided the patient is in the best possible shape, laparotomy should be carried out.

The preoperative preparation of the patient is extremely important and laboratory tests such as the eosinophil count, electrolyte pattern and diuresis test of Robinson-Power and Kepler should be carried out in order to determine the possibility of late adrenal insufficiency. To prevent acute adrenal insufficiency from occurring throughout the operation or immediately following removal of an adrenal tumor, the patient should be given glucose and salt solution prior to the operation. 10 cc. of whole corticoadrenal extract should be given intramuscularly the night before surgery and again in the morning prior to sending the patient to the operating room. An intravenous drip containing glucose and saline should be started at the time of operation and prior to opening the adrenal cavity, 10 cc. of adrenal cortex extract are given intravenously. If the opposite gland is atrophic or absent, portions of the involved gland should be left if at all possible. If this is not possible adrenal insufficiency should be anticipated and treatment carried out immediately.

Surgical Approach.—Standard surgical approaches to the adrenals are (1) extra-peritoneal nephrectomy incision, (2) the longitudinal lumbo-dorsal incision, (3) the transperitoneal approach through either a transverse or vertical incision of the abdomen and (4) the transpleural route. In our cases the transperitoneal approach has been preferred because it affords visualization of both adrenals as well as the entire abdominal cavity to rule out the possibility of ectopic adrenal tissue. This incision has permitted also better visualization and clamping other vessels of the adrenal before manipulation or removal of the adrenal neoplasms. The abdominal incision should be closed with interrupted stitches of non-absorbable sutures and possibly steel sutures are the best in this regard for these patients have a tendency for infection and their wounds do not heal kindly or readily. This is interesting in light of the experimental evidence to indicate the depressing action of cortisone upon wound healing in experimental animals.

Discussion

Dr. Harvey Nelson: Such an interesting and comprehensive presentation of a condition that most of us see infrequently certainly warrants some comment and discussion. If you have had no more experience with adrenal tumors than I, you are probably more than interested. I recall one recent case that we had. A patient, nineteen years old, came in only because her abdomen had enlarged so that she could not get her dresses buttoned any longer. Physical examination revealed a very large tumor. In the course of our diagnostic studies, an intravenous pyelogram was taken which revealed a large adrenal tumor pushing the kidney down into a horizontal position but still revealing a functioning kidney. In order to remove the tumor, together with the kidney, a "U"-shaped incision was necessary extending all the way from the costo-vertebral angle posteriorly around the lower ribs to the xiphoid process anteriorly. Postoperatively, the patient got along quite well for six months, when she developed some pelvic metastases which seemed to arise from the region of the ovaries. A panhysterectomy was done, removing also a considrable amount of pelvic peritoneum. On the occasion of each operative procedure, she seemed to respond quite well to x-ray therapy. Subsequent to the second operative procedure, she was again all right for a period of six months when she began to develop pains in her lower extremities which ultimately progressed to a partial paralysis due to metastases in the dorsal region of her spine and external to the dura. A laminectomy

Action of DRAMAMINE on Vestibular Function

"Dimenhydrinate [Dramamine] produced a marked and reversible depression of vestibular response. . . ."*

In a study of the action of Dramamine on vestibular function, Gutner and his associates found that Dramamine "significantly delayed the onset of nystagmus, shortened the duration of nystagmus and increased the milliamperage necessary to effect tilting."

The great effectiveness of Dramamine in motion sickness, they state, ". . . is probably related primarily to its ability to depress vestibular function. . . ."

DRAMAMINE®

BRAND OF DIMENHYDRINATE

—for prevention and treatment of motion sickness—

Now available in these dosage forms:
- Tablets — 50 mg.
- Liquid — 12 mg. per 4 cc.
- Average dose — 50 mg.

RESEARCH IN THE SERVICE OF MEDICINE SEARLE

◆ Reports and Announcements ◆

AERO MEDICAL ASSOCIATION

The twenty-third annual meeting of the Aero Medical Association was held at the Statler Hotel, Washington, D. C., March 17 to 19. Attending the meeting for the first time were aviation medicine representatives from twenty other nations.

A full program of scientific papers, exhibits and demonstrations showed many of the latest trends and developments in the field of aviation medicine. In addition, the space medicine group of the organization presented a series of discussions in their specialized field of research.

AMERICAN COLLEGE OF ALLERGISTS

The eighth annual meeting of The American College of Allergists will be held this year at the William Penn Hotel in Pittsburgh, Pennsylvania, on April 7, 8 and 9. In addition to twenty addresses on general topics and special scientific investigations, there will be round tables at luncheons and sectional meetings devoted exclusively to the psychosomatic aspects of the allergic patient, allergy in infants and children, allergic manifestations in the skin, as well as those seen in the eye, ear, nose and throat.

An innovation for meetings of allergists will be a session devoted to the problems of the allergic patient as met in modern industrial medicine. All reputable physicians are welcome to attend. For more particulars, write The American College of Allergists, LaSalle Medical Building, Minneapolis 2, Minnesota.

GRADUATE COURSE IN ALLERGY

On April 4, 5 and 6 at Pittsburgh, Pennsylvania, The American College of Allergists will offer an instruction course in allergy. Some sixty well-known authorities in the field will give addresses, clinical talks and demonstrations. The program has been designed for physicians in other fields of practice, especially those in general practice, so that they may learn to recognize and manage the allergic component in the complaints of their patients.

For further information and a copy of the program, write the office of The American College of Allergists, LaSalle Medical Building, Minneapolis 2, Minnesota.

MANUSCRIPT EDITING SERVICE

To improve medical journalism, the American Medical Writers' Association has recently established the first Manuscript Editing Service to be conducted by a medical association in the United States. For a small fee, the Association will edit and criticize medical manuscripts (up to 5,000 words). Its aim is to help authors carry out the dictum of Sydney Smith: "The writer does the most who gives his reader the most knowledge and takes from him the least time." The Association is a nonprofit organization with no salaried officers. Its membership includes a large group of well-known medical editors and writers. Principal purpose of the group is "to help maintain and advance high standards of medical literature."

Further details of the new Manuscript Editing Service may be obtained from the Secretary, Harold Swanberg, M.D., 209-224 W.C.U. Building, Quincy, Illinois.

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

The regular meeting of the Minnesota Society of Neurology and Psychiatry was held at the Town and Country Club in Saint Paul on March 11. The scientific program included the following presentations:

"Neurophysiologic Testing in Parkinsonism," inaugural thesis by Dr. Andrew J. Leemhuis, Minneapolis.

"A Psychosomatic Study of a Case of Acute Intermittent Porphyria," by Dr. C. Knight Aldrich and Dr. John S. Visher, both of Minneapolis.

"An Electroshock Fatality in an Acute Excitement Complicated by Bronchiectasis," by Dr. B. C. Schiele, Minneapolis.

MINNESOTA TUBERCULOSIS AND HEALTH ASSOCIATION

The name of the Minnesota Public Health Association, the state Christmas Seal organization, has been changed to the Minnesota Tuberculosis and Health Association. Two reasons were given for the inclusion of the word "tuberculosis" in the name of the organization's name: (1) there has been some confusion because of the previous name's similarity to that of the Minnesota Department of Health and other health agencies, and (2) Christmas Seals, the sole means of support of the association, are sold primarily to finance the fight against tuberculosis.

The previous name, Minnesota Public Health Association, was taken in 1914 because the group's leaders wanted to emphasize the importance of an all-out health program to defeat tuberculosis.

County associations affiliated with the state organization are also changing their names from county public health associations to county tuberculosis and health associations.

MINNESOTA WELFARE CONFERENCE

The Minnesota Welfare Conference will be held at the Hotel Saint Paul, Saint Paul, March 31 to April 2.

Several sessions during the annual meeting will be devoted to health and medical discussions. The following items will appear on the program:

"Rehabilitation: The Community's Responsibility" by Mr. Eugene Taylor, assistant professor of the Depart-

ment of Physical Medicine and Rehabilitation, New York University College of Medicine. March 31, 2:15 to 3:15 p.m.

"Rehabilitation of the Aging" by Dr. Murray B. Ferderber, Department of Physical Medicine, University of Pittsburgh. April 2, 10:15 to 11:30 a.m.

"Hospital Services in Rehabilitation in Minnesota" by Dr. Robert Barr and Dr. Helen Knudson, Minnesota Department of Health. April 2, 3:30 to 5:00 p.m.

Members of the Minnesota State Medical Association are invited to attend these sessions.

CONTINUATION COURSES

Obstetrics.—A course in obstetrics for specialists in that field will be held at the Center for Continuation Study at the University of Minnesota on April 17 to 19. The visiting faculty member for the course will be Dr. S. M. R. Reynolds, physiologist, Department of Embryology, Carnegie Institution of Washington, Baltimore, and the remainder of the faculty for the course will be announced at a later date. Dr. Reynolds will deliver the annual Duluth Clinic Lecture on the subject, "Newer Concepts of Fetal Circulation," on April 18.

Pediatrics.—The University of Minnesota will present a course in pediatrics on April 21 to 23. The course will be presented at the Center for Continuation Study and is intended primarily for physicians specializing in pediatrics. Emphasis will be placed on infectious diseases as they occur in pediatric practice. Dr. John M. Adams, professor, Department of Pediatrics, University of California, Los Angeles, formerly a member of the Department of Pediatrics at the University of Minnesota, will be the visiting faculty member for the course. Dr. Adams will also deliver the annual Clarence M. Jackson Lecture sponsored by the Phi Beta Pi medical fraternity on the subject, "Respiratory Diseases—Changing Concepts."

Eye, Ear, Nose and Throat.—The University of Minnesota will present a continuation course in eye, ear, nose, and throat problems at the Center for Continuation Study from May 12 to 14. The course is intended for physicians engaged in general practice. One day will be devoted to the consideration of ocular problems, and the remainder of the time will be devoted to those ear, nose, and throat conditions which are most frequently seen in general practice.

Dr. Erling W. Hansen, clinical professor and director, Division of Ophthalmology, and Dr. George M. Tangen, clinical assistant professor, Division of Otolaryngology, will join in the direction of the course, and the remainder of the faculty will include clinical and full-time members of the staff of the University of Minnesota Hospitals.

Allergy and Hematology.—The University of Minnesota will present a course in allergy and hematology at the Center for Continuation Study on May 15 to 17. The course is intended primarily for physicians engaged in general practice but will be of interest to internists and pediatricians as well. One day will be devoted to the consideration of hematologic problems, and the remainder of the session will deal with diagnosis and management of allergic disorders.

Dr. Will Cook Spain, an outstanding authority in the field of allergy, will be the visiting faculty member for the course, while the remainder of the faculty will include clinical and full-time members of the staff of the University of Minnesota Medical School and the Mayo Foundation. The course will be presented under the direction of Dr. C. J. Watson, professor and director, Department of Medicine, at the University of Minnesota Medical School.

HENNEPIN COUNTY SOCIETY

Dr. Claude J. Ehrenberg, Minneapolis, will be installed as president of the Hennepin County Medical Society next October, succeeding Dr. William R. Jones.

Other officers elected at a meeting of the society in Minneapolis on February 4 include Dr. Horatio B. Sweetser, Jr., first vice president; Dr. Dale H. Correa, second vice president; Dr. L. Haynes Fowler and Dr. Robert E. Priest, members of the board of directors; Dr. Thomas J. Kinsella and Dr. Reuben A. Johnson, board of censors; Dr. Lawrence R. Boies and Dr. Thomas Lowry, board of ethics; Dr. James A. Blake and Dr. Frank R. Hirschfield, board of trustees; Dr. Ralph H. Creighton, Dr. Willard D. White and Dr. Elmer T. Ceder, delegates to the Minnesota State Medical Association.

MINNESOTA ACADEMY OF MEDICINE

(Continued from Page 243)

one could scarcely advocate gastric resection on a well person in order to prove that his healed gastric ulcer was definitely benign. Furthermore, as Dr. Wangensteen has indicated, gross and histologic studies of a specimen may be in error and therefore in some cases a clinical evaluation of the benignancy or malignancy of an ulcer may be more accurate.

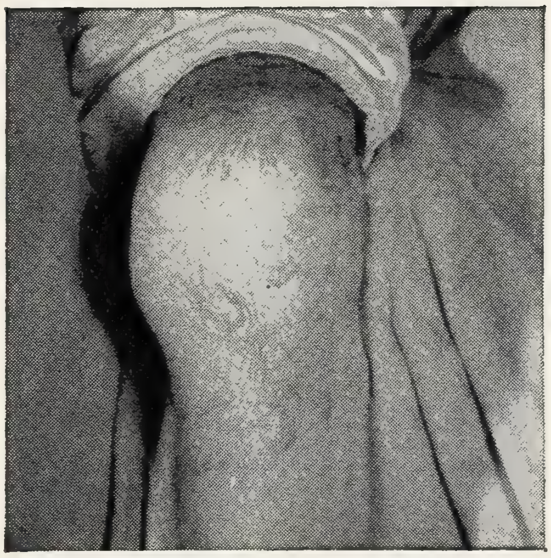
I wish to re-emphasize that this study was not done to determine how gastric ulcers should be treated but merely to determine the incidence of malignancy in the garden variety of gastric ulcer seen in private practice. This is less than 2 per cent. In order to make this study more valuable we will continue to follow these same patients for another ten years as well as to add new cases to the group.

The meeting was adjourned.

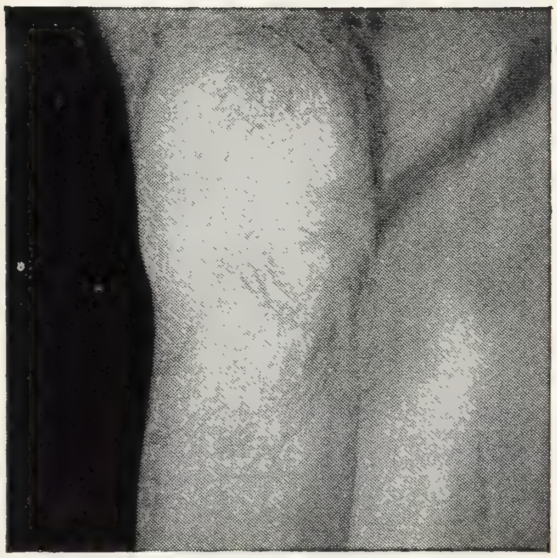
Wallace P. Ritchie, M.D., *Secretary*

Cortone®

Can be used Safely in the Prolonged Control of Rheumatoid Arthritis



BEFORE TREATMENT:
Periarticular swelling and hydrarthrosis



AFTER TREATMENT:
Diminution of pain, increased mobility, and visibly decreased effusion and swelling

Rehabilitation Achieved Through Conservative Dosage

Management in Everyday Practice

The use of simple laboratory tests (sedimentation rates, urinalyses, blood counts, blood pressure, and frequent weight recordings), individualized adjustment of dosage, and careful clinical observation will permit most patients to benefit materially . . . without fear of undesired effects.

Effective Antirheumatic Response

Effective antirheumatic response was achieved in all 100 patients in a long-term study at the Mayo Clinic. More than 50 of these arthritics were maintained on 50 mg. or less daily. In no case was it necessary to withdraw the hormone.

Ward, L. E., Slocumb, C. H., Polley, H. F., Lowman, E. W., and Hench, P. S.: *Proc. Staff Mtgs., Mayo Clinic* **26:** 361, September 26, 1951.

Woman's Auxiliary

CHAIRMAN REPORTS ON PUBLIC RELATIONS PROGRAM

Mrs. L. J. Leonard, Minneapolis

The recruitment of nurses occupies position number one on the auxiliary's public relations program this year. At the AMA Public Relations Conference held in Los Angeles last December, which was attended by well over five hundred, $10,000 was subscribed to the nurse recruitment program. The national auxiliary contributed $500 to the American Nurses Association last year to aid in the development of their program and over 300 scholarships and loans to student nurses have been given thus far.

Most of the county auxiliaries are aware of the great need for nurses and are making every effort to acquaint young women students in their various communities with the requirements and advantages of the profession, also offering whatever aid they can. It has been suggested that the auxiliary go one step farther and urge women's organizations, such as the PEO, Woman's club or other service organizations to sponsor student nurses.

A new training program will soon come from national headquarters which will equip nurses to make a better approach to people who come to the doctor's office. It is urged that this be given fullest support.

Also, if it would come under auxiliary jurisdiction, try to get a good representative nurse to attend the National Nurses Convention in Atlantic City in June.

It is vital that members urge their husbands to contribute to medical schools. Their need is great and if aid is not given, they may be forced to accept federal grants. Legislation is constantly being advocated in this direction. Auxiliaries all over the country are beginning to contribute. "Check your budget for a little surplus," says the national public relations chairman, Mrs. Theodore Heinz. "We would like $100 from each state auxiliary."

Remember that socialized medicine is not a dead issue. To quote Dr. Louis Bauer, AMA's president-elect:

> "This country is fast moving down the road marked Socialism. 1952, a presidential election year, offers physicians and wives an opportunity to whip socialism at the polls. Every physician, as a citizen, should resolve to become actively engaged in this campaign. Socialism can easily come to this country without a vote; it can come by default."

National statistics show that less than fifty per cent of qualified voters went to the polls and the medical profession had the shameful record of only thirty-six per cent. At the state Board meeting in January, at the Curtis hotel, Minneapolis, a chairman reported that through efforts of their auxiliary, the vote of the medical profession was brought up to eighty-three per cent, which shows what can be accomplished if the effort is made.

The American Medical Association is constantly providing new available literature. "A Doctor for You" is a recent one and another dealing with the Code of Ethics which will be called "The Code Your Doctor Lives By," will be available soon. It has been suggested that each auxiliary appoint a distribution chairman to superintend the delivery of these pamphlets and also reprints of magazine articles which are available, to the libraries in her town, to the hospital waiting rooms, school teachers, ministers and officers of women's groups. They are wonderful materials to hand out at medical society booths at county fairs. Now is the time to plan in advance to make full use of these excellent PR aids. Public opinion moulds slowly but surely. Be a vigilant worker.

A gift suggestion for a physician husband: One of AMA's new plaques for use in doctor's offices. It is designed to encourage patients to talk freely with their physician in order that misunderstandings about services or fees may be avoided. The plaque costs $1 postpaid.

COUNTY AUXILIARY HOLDS ANNUAL NURSE TEA

Members of the Mower County Medical auxiliary recently attended the second annual tea for sophomore, junior and senior girls interested in nursing or its allied branches. The committee in charge of arrangements consisted of Mrs. C. L. Sheedy, Mrs. P. A. Lommen, Mrs. Edward C. Sargent and Mrs. T. M. Seery.

Signing blood donors, arranging appointments and helping at the blood donor station have also become auxiliary projects.

STATE COMMITTEE CONTINUES WORK

Mrs. L. G. Culver, Saint Paul

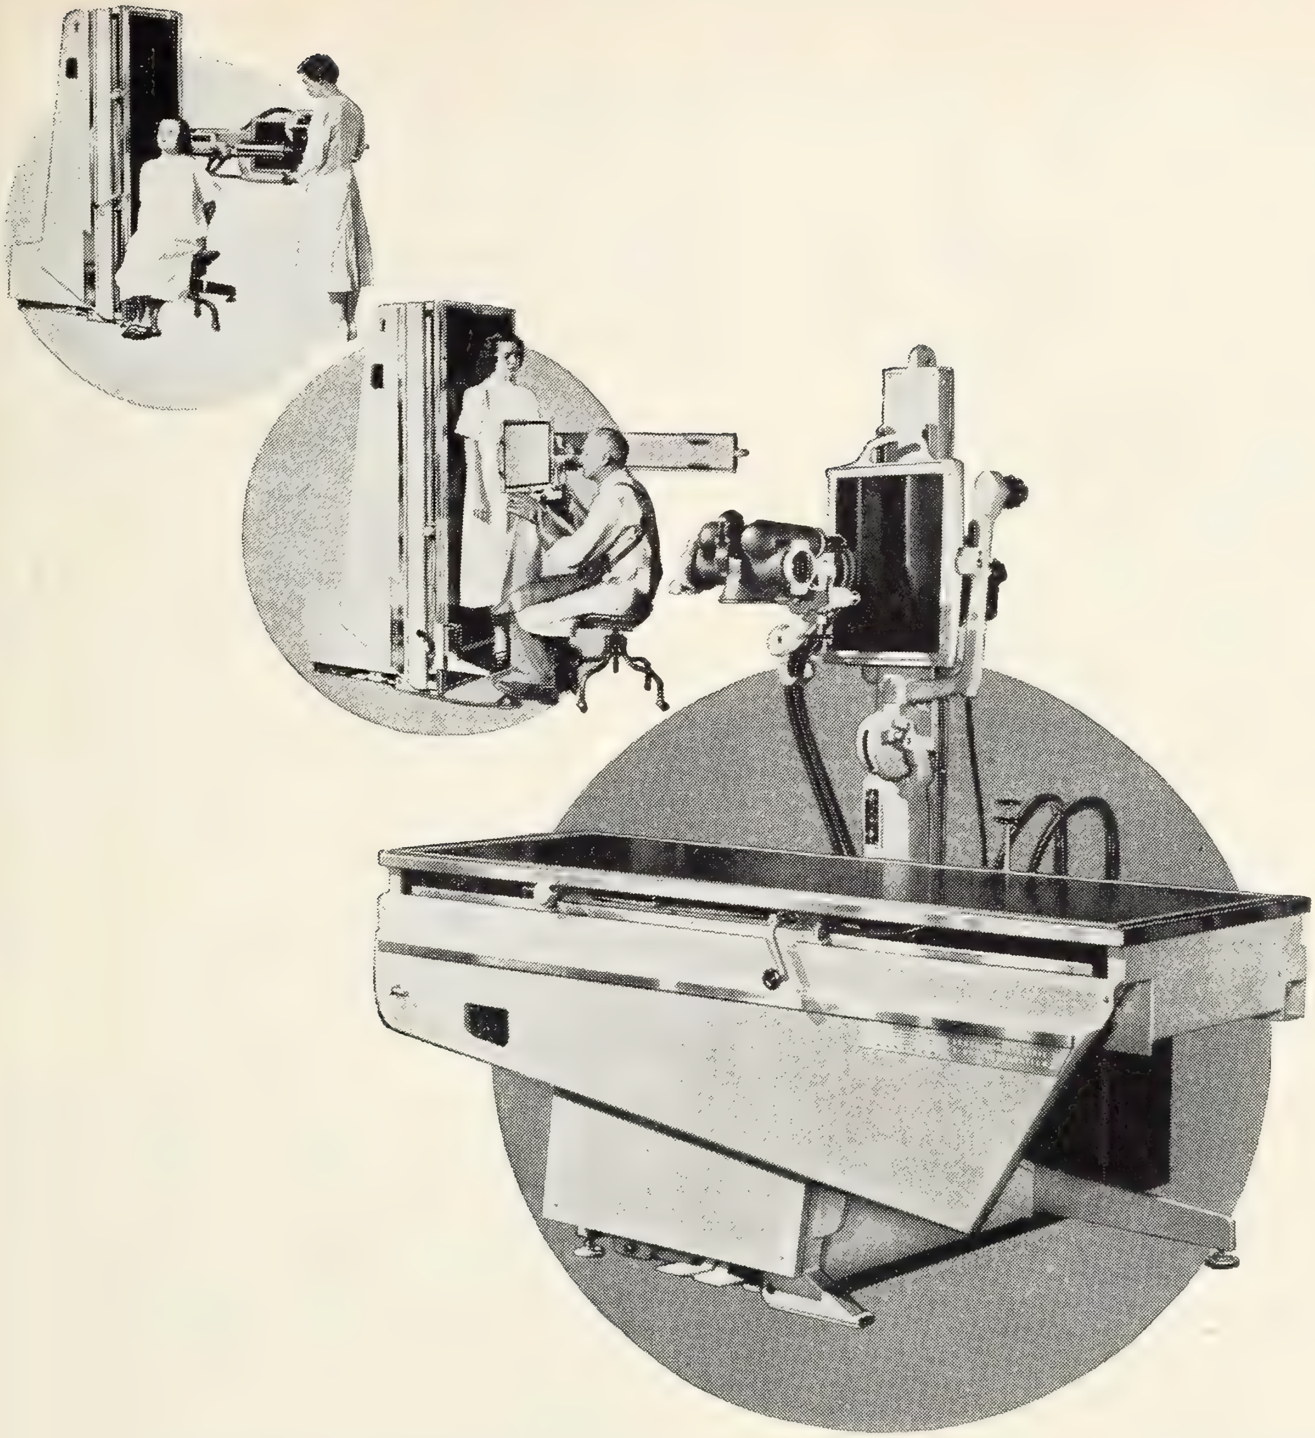
The Committee on Medical and Surgical Relief of the Woman's Auxiliary to the Minnesota State Medical Association is continuing in the collection, from doctors' offices, of surplus medical and surgical supplies. A letter has been sent to county committee chairmen, encouraging continuation of the work on a county basis.

Mr. Pedro Velasco, 3009 Ewing Avenue North, Robbinsdale, Minnesota, is still anxious to receive supplies so that as soon as two tons of supplies have been accumulated, he will be able to ship them to the Philippines.

In 1950, 1,799,800 Americans were injured in traffic accidents.

* * *

Speeding on U. S. streets and highways last year killed 13,300 men, women, and children.



ONE TUBE DOES DOUBLE DUTY IN THIS MAXICON

Versatile is the word for this Maxicon. Capable of a wide range of diagnostic service, it has ample facilities for both radiography and fluoroscopy, horizontally and vertically.

Hand-tilt or motor-driven, the single-tube radiographic and fluoroscopic table is designed for operation with 100 or 200 ma generators. Its table-mounted tube stand makes it compact — ideal for small room.

In Memoriam

NORBERT P. BLOCHOWIAK

Dr. N. P. Blochowiak, a young physician of Rushford, Minnesota, tragically met death on January 20, 1952, when his car slid into a freight engine. He was only twenty-nine years of age and had come to Rushford just two and a half years ago, after serving an internship at Ancker Hospital in Saint Paul.

Dr. Blochowiak was born June 29, 1922, at Pulaski, Wisconsin. He obtained his medical degree from the University of Minnesota Medical School in 1948, his study having been interrupted by two years in the army.

He had become an active worker in community affairs in the short time he had lived at Rushford and belonged to the Commercial Club, the Lions Club, the American Legion. He was a member of the Winona County Medical Society, the Minnesota State Medical Association and the American Medical Association. Lately, he had taken a leading part as chairman of the investigating committee for Rushford's new Youth Center.

On June 15, 1946, he married Beverly Bornitz of Lamoille. He leaves his wife and two small children, Kenneth Robert and Patricia Ann. His mother, seven brothers and two sisters also survive him.

EDWARD C. BOXELL

Dr. Edward C. Boxell, Saint Paul, died January 13, 1952, at the age of eighty-eight.

Dr. Boxell was a member of the Class of 1894 at the University of Minnesota medical school. He practiced for a short time at Annandale and Saint Paul Park before moving to Saint Paul.

Dr. Boxell is survived by his wife, Mary; and a son Allan, both of Saint Paul.

HANS JOHNSON

Dr. Hans Johnson of Kerkhoven, Minnesota, died January 13, 1952 in the Abbott Hospital, Minneapolis, following injuries received December 17, 1951, in an automobile accident near Spirit Lake, Iowa. He was seventy-one years of age. His wife, Estelle, seriously injured in the crash, is recovering at her home.

Dr. Johnson was born January 14, 1881 at Royalton, Minnesota. He graduated from the University of Minnesota medical school in 1904. He practiced at Middle River, Minnesota, and at Murdock, Minnesota, before he located at Kerkhoven in 1907. He was honored last summer by his fellow citizens with a "Dr. Johnson Appreciation Day."

He took an active interest in local affairs, having been mayor of Kerkhoven in 1917-18 and again in 1933-35. He served on the school board from 1918 until his death and was president of the board from 1927 on. He also served as health officer and as physician on the Swift County Selective Service Board.

Dr. Johnson married Estelle Quam of New London, Minnesota, June 6, 1907. She and four children, Dr. John W. Johnson of St. Louis Park, Minnesota, Lester of Carmel, Indiana, H. Clinton of Huntington Woods, Michigan, and Mrs. Merle (Dagmar) Gribble of Honolulu survive him. One son, Gordon, was killed in action at Duren, Germany, in 1944.

OSCAR O. BURTON

Dr. Oscar O. Burton, formerly of Albert Lea, died at his home in Brattleboro, Vermont, December 31, 1951.

Oscar Burton was born in St. Albans, New York, and came to Alden, Minnesota, with his parents about 1876.

Dr. Burton married Alice Hibbs and practiced in Albert Lea for some ten years before moving to Florida for his health. At one time, he was secretary of the Freeborn County Medical Society.

From Florida, Dr. Burton moved to Wellesley, Massachusetts, and then to Westminster, Vermont. For the last few years, he has been health officer and town physician for the city of Brattleboro.

M. W. KEMP

Dr. M. W. Kemp, former superintendent of the State Hospital at Moose Lake, Minnesota, died at his home in Madison, Indiana, February 6, 1952, of a heart attack. He was fifty-six years of age.

Dr. Kemp spent eight years as superintendent of the State Hospital in Moose Lake from 1938 to 1946. Prior to coming to Moose Lake, he was assistant superintendent of the Fergus Falls state hospital from April, 1927, to October, 1935, when he resigned to accept the superintendency of the Anoka state hospital. He left Moose Lake in 1946 to become superintendent of the hospital at Madison, Indiana.

Dr. Kemp is survived by his wife and one daughter, aged fourteen.

JOHN M. ORT

Dr. John M. Ort, former member of the staff of the Mayo Clinic, died on August 25, 1951, of a cerebrovascular accident.

John M. Ort was born May 31, 1896, at Home City, Ohio. He received the degree of M.S. in 1919, and Ph.D. in 1924 from Ohio State University, Columbus. He was instructor at Cass School of Applied Science in Cleveland from 1919 to 1922, was assistant in physical chemistry at Ohio State University from 1922 to 1923, and a Du Pont fellow in chemistry at Ohio State University in 1923-1924. He came to the Clinic as first

Therapy for Vascular Headache to Reverse the Physiologic Disturbance

Headache, a problem encountered in all kinds of medical practice, may occur in association with any of a variety of disorders, some organic, other purely functional.

Among the several types, functional headaches present the greatest problem because of their obscure etiology and recurrent nature.

Among these are:

Migraine (both classical and variant forms)
Tension headache
Psychogenic headache
Histaminic cephalgia

Wolff and his co-workers established that the pain of these headches is due to disturbance of the tonus of cranial blood vessels — hence the term *vascular headaches.*

The craniovascular changes associated with the several phases of the typical migraine attack are:

Vasoconstriction — to which the visual prodromata are attributable. It is possible to abort the attack during this phase in all but a few cases. (See treatment below.)

Vasodilatation — as the vessels lose their tone, exaggerated pulsations set in, resulting in the throbbing pain which characterizes vascular headache. Treatment for the attack is still effective during this phase. (See below.)

Vessel Edema — if the vasodilation continues for too long, vessel walls become edematous; this changes the character of the pain to a steady, intense aching. The attack can now no longer be checked, even with maximum dosage of specific drugs. *Moreover, sustained headache often induces reflex neck muscle tension, a source of residual pain.*

Therapy: 1. Reduce the frequency of attacks — psychotherapy and regulation of living habits to avoid fatigue and nervous tension.

2. Relieve the acute attack — of the numerous drugs which have been tried, ergotamine and its derivative preparations have proved most effective. The newest product is oral tablets of Cafergot®, N. N. R. (ergotamine with caffeine 'Sandoz'). When dosage is adjusted to the needs of the individual, Cafergot will give good relief in 85% of cases. It enables a greater number of patients to benefit from early administration since the oral route simplifies treatment as compared to parenteral therapy.

The dosage procedure is:

1. Take 2 tablets at first sign of the attack.
2. If attack continues, take one additional tablet every ½ hour until attack is terminated *(max. 6 tabs. per attack).*

Many migraine patients delay taking medication until the attack is at its height. Explicit dosage instructions may be forgotten unless the patient comes to realize their importance. Therefore, to encourage adherence to correct procedure, we have prepared pads outlining detailed dosage instructions. Supplies of these INSTRUCTION SLIPS will gladly be sent upon request.

(Continued from Page 254)

assistant in the Division of Physics on July 22, 1924. He was appointed assistant professor of biophysics, the Mayo Foundation, July 1, 1925.

Dr. Ort left the Clinic and Foundation in September, 1932, at which time he became engaged in physical chemical research for Swift and Company, Chicago, until August 15, 1933. Since that time his work has included physical chemical research for E. R. Squibb and Sons, Brooklyn, New York, and the directorship of research at the Carroll Dunham Smith Pharmacal Company, New Brunswick, New Jersey.

Dr. Ort was a member of the American Chemical Society, the American Society of Biological Chemists, the American Institute of Chemists, the American Association for the Advancement of Science and Sigma Xi.

MALCOLM C. PFUNDER

Dr. Malcolm C. Pfunder of Minneapolis died on January 23, 1952, at the age of sixty-four.

Born at Two Creeks, Wisconsin, January 19, 1888, Dr. Pfunder received the degrees of B.S. and B.A. at Ripon College and an M.D. at Rush Medical College in 1919. He interned at Miles City Hospital, Miles City, Montana, and at Worrall Hospital, Rochester, Minnesota, after which he took postgraduate training in Ophthalmology and Otolaryngology for eighteen months at the Mayo Foundation.

After practicing from 1922 to 1929 at Miles City, Dr. Pfunder moved to Minneapolis where he practiced his specialty. He had the appointment of Assistant Clinical Professor of Ophthalmology at the University of Minnesota Medical School and was chief of the Eye, Ear, Nose and Throat service at the Minneapolis General Hospital. He was a member of the American College of Surgeons, the Pan American Association of Ophthalmology, the Hennepin County Medical Society of which he was a past president, the Minnesota Academy of Ophthalmology and Otolaryngology, the Minnesota State Medical Association and the American Medical Association.

Dr. Pfunder held memberships in the Minneapolis Athletic Club, the National Skeet Shooting Association, the Big Game Club, the Zuhrah Temple of the Shrine, the Scottish Rite Lynnhurst Masonic Lodge, Alpha Omega Alpha and Phi Chi. He was a member of Knox Presbyterian Church.

Surviving are his wife, Mrs. Edna Gilkey Pfunder; a daughter, Mrs. Curtis H. Carlsen, and a son, Malcolm G. Pfunder.

GEORGE E. RUNNERSTROM

Dr. George E. Runnerstrom, former Minneapolis physician, died January 26, 1952, in Engelwood, California. A stroke was given as the cause of death. Dr. Runnerstrom had been in ill health for some time.

George Runnerstrom was born in Otisco township, Minnesota, in 1892 and attended Waseca schools. He obtained his M.D. degree at the University of Minnesota.

He was married in 1918 to Mata Mills of Minneapolis, who survives.

Dr. Runnerstrom served on the staff at the Fort Snelling veterans hospital for twenty-two years, until 1939 when he went to Washington, D. C., where he continued in veterans work until 1945. At that time, in failing health, he retired from medical practice and moved to California.

In addition to his widow, he leaves one son Warren, at home, and one daughter Ruth, now married and living in St. Louis, Missouri.

CARL B. TEISBERG

Dr. Carl B. Teisberg, examining physician for the Minnesota Athletic commission, died Saturday, February 9, 1952, at his home in Saint Paul. He was seventy-two years old.

Practicing physician since 1910 in Saint Paul, Dr. Teisberg was a graduate of Luther College at Decorah, Iowa, and the University of Minnesota medical school. He practiced in Pine City prior to moving to Saint Paul.

Survivors include the widow, Mary V.; a daughter, two sons, four sisters and three brothers.

T. J. TRUTNA

Dr. T. J. Trutna, practicing physician in Silver Lake, Minnesota, since 1906, died at his home Friday morning, February 8, 1952. He was seventy-three years of age.

Dr. Trutna had practiced medicine in Silver Lake more than forty-five years, and had been a resident of that town since 1892 when he came with his family to Minnesota from Wahoo, Nebraska. He was a veteran of World War I, and organizer and first commander of American Legion Post No. 142 in Silver Lake.

Members of the post served as honor guards at the funeral service and sounded taps at the graveside service.

Dr. Trutna studied medicine at the University of Minnesota and came to Silver Lake in 1906 after one year as an intern at Asbury Hospital in Minneapolis.

Dr. and Mrs. Trutna were married January 1, 1919, while the doctor was home on furlough.

Survivors include his wife, Eleanor; two sons, Raleigh of Hastings, Minnesota, and Roger of Saint Paul; and two brothers, Anthony H., Mohall, North Dakota, and Frank, West Union, Minnesota.

Dr. Winston R. Lindberg is now associated with his father, Dr. A. C. Lindberg, at 600 Physicians and Surgeons Building, Minneapolis, in the practice of ophthalmology and ophthalmic surgery. The younger Dr. Lindberg recently completed a two-year residency at John Gaston Hospital, Memphis, Tennessee.

* * *

Dr. W. C. Stillwell, of the Mankato Clinic, Mankato, was among those who attended the nineteenth annual meeting of the American Academy of Orthopedic Surgeons at the Palmer House, Chicago, from January 26 through 31.

* * *

Dr. Ralph F. Mach, formerly of Rush City, moved to Pine City early in February. A graduate of the University of Minnesota Medical School, he served his internship at Mercy Hospital, Loyola University Clinic, Chicago. He began practice at Foley in 1947, then moved to Rush City in 1948 and was associated in practice with Dr. J. E. Halpern for four years.

* * *

Word was received early in February that **Dr. David M. Berkman** has retired from the staff of the Mayo Clinic, Rochester, and is now living at Oronoco.

* * *

The **Minnesota Tuberculosis and Health Association** (formerly called the Minnesota Public Health Association) has established the H. Longstreet Taylor grant of $7,500, to be made annually to the University of Minnesota for tuberculosis research. It will be administered by Dr. J. Arthur Myers,, professor of preventive medicine and public health at the University. Dr. H. Longstreet Taylor was largely responsible for the initiation of the campaign for the prevention of tuberculosis in Minnesota.

* * *

After practicing internal medicine at Saint Paul for the past five years, **Dr. John C. Hays** has moved to Colorado Springs, Colorado, where he is now associated with the Colorado Springs Medical Center.

* * *

Mr. W. B. Schoenbohm has been selected as director of the **Minnesota Society for Crippled Children and Adults.** Mr. Schoenbohm was formerly director of the hospital for severely handicapped children at the University of Iowa and president of the Iowa Society for Crippled Children and Adults. He succeeds Mr. Robert Booth as director of the Minnesota society.

* * *

More than 150 guests attended an open house in Winona on February 5 at which **Dr. and Mrs. W. F. C. Heise** celebrated their fiftieth wedding anniversary. Following the open house, a family buffet dinner continued the golden wedding anniversary celebration.

Dr. Heise has practiced medicine at Winona since his graduation from Rush Medical College. He and his five sons, all physicians, founded the Heise Clinic at Winona.

* * *

Dr. Ezra V. Bridge, superintendent of the Cannon Falls Sanatorium, spoke on the "Modern Treatment of Tuberculosis" at a joint meeting of several nurses groups at St. Lucas Hospital, Faribault, on February 11.

* * *

Dr. Abbott Skinner and **Dr. Charles Eginton** have become associated in the practice of surgery and have established offices at 666 Lowry Medical Arts Building, Saint Paul. Dr. Skinner received his medical training at Harvard Medical School and took his postgraduate study at Ancker Hospital, Saint Paul. Dr. Eginton, a graduate of the University of Minnesota Medical School, did postgraduate work as a fellow in surgery at the Mayo Foundation, Rochester. Both physicians have M.S. (Surgery) degrees and are diplomates of the American Board of Surgery.

* * *

Mr. G. Ray Higgins, formerly director of student unions at the University of Minnesota, has been appointed executive secretary of the **Minnesota Heart Association.** He succeeds Mr. Fred L. Wheeler, former executive secretary.

* * *

Dr. F. W. Behmler, Morris, was elected president of the Minnesota State Board of Health at its meeting in Minneapolis on February 5. Dr. Behmler has been a member of the board since 1940 and was recently reappointed for another three-year term. He served as vice president of the board for several years. He has practiced medicine at Morris for fifteen years.

* * *

Dr. W. O. Finkelnburg, Winona, discussed the human heart and cardiac problems of the middle-aged at a businessmen's meeting in Winona on February 6. The showing of motion pictures and the distribution of literature on the subject were included at the meeting.

YOUR *TOP LAYER* INCOME

TAXABLE INVESTMENT INCOME is your most expensive income since, under our progressive income tax system, it is this *"Top Layer"* income that pays the heaviest taxes.

There is little a taxpayer can do about his taxable income received from:

Professional Income
Salaries
Business Profits
Dividends from Business

These are main sources of revenues—your basic income. *"Top Layer"* income, however, your investment income, is something that you definitely have control over in that it is within your power to give such income either a "taxable" or a "tax-free" status.

The income from investments which is subject to taxation actually shrinks in yield whenever your professional income increases and forces this taxable *"Top Layer"* income into a higher bracket. In other words, the more your active earning power is increased, the greater percentage of your taxable investment income will be paid out in taxes.

Tax-free income is interest income on Municipal Bonds. This interest is exempt from all present Federal Income Taxes and consequently provides a *"Top Layer"* income that remains constant regardless of changes in other income or tax rates.

The two following examples clearly demonstrate the effect of Federal Income taxes on *"Top Layer"* income:

> If you are in the $12,000-$14,000 individual income tax bracket and purchase an investment to yield 2.50% you will realize about 1.30% if the income is taxable but will receive the full 2.50% if it is not taxable.
>
> If you are in the $20,000-$22,000 individual income tax bracket and purchase an investment to yield 2.50% you will realize about .95% if the income is taxable but will receive the full 2.50% if it is not taxable.

We shall be pleased to send you information and descriptive circulars pertaining to Municipal Bonds that we have currently available for sale.

hospital and as a civic leader, at special ceremonies held in January. The occasion was the presentation of a framed picture of Dr. Doms to the Murray County Memorial Hospital. The picture was presented by the Slayton Civic and Commerce Association, of which Dr. Doms was an organizer and past president, and the Murray County State Bank, of which he was a director for a number of years.

* * *

Dr. Viktor Wilson, of the Minnesota State Health Department, discussed activities of the Health Department in general with a group of physicians and medical students taking graduate work at the University of Minnesota when they made a tour of health units and a hospital in Rochester early in February. Countries represented in the group were Turkey, Formosa, Thailand, Mexico, Ceylon, and Germany. Local health and sanitation techniques of the Rochester-Olmsted County health unit, the health center, St. Mary's Hospital, and the new sewage treatment plant in Rochester were objects of special interest to the students who will carry the knowledge thus gained back to their own countries in setting up similar health units.

* * *

Dr. Walter M. Boothby, of Albuquerque, New Mexico, formerly of Rochester, Minnesota, was awarded the order of Commander of the North Star by the King of Sweden the latter part of January. The ceremony of presentation was made by Gunnar Dryselius, Swedish Consul at Houston, Texas, at a reception held in the home of Dr. and Mrs. William R. Lovelace, II, also former Rochester residents. Dr. and Mrs. Boothby have lived in Albuquerque since last November, when Dr. Boothby became a member of the Lovelace Foundation for Medical Education and Research at the invitation of Dr. Lovelace, former pupil of Dr. Boothy.

CORRECTION

Two errors, which occurred in printing the list of Physicians Licensed in 1951 in the December, 1951, issue of MINNESOTA MEDICINE have just been called to our attention.

On Page 1192, under the subhead "Reciprocity Candidates," the name immediately following that of Buchanan, Gerald S. should be spelled as follows: ELLERTSON, Jr., Leonard Melvin.

On Page 1196, under the subhead "National Board Candidates," the name immediately following that of Lovelace, Jr., Daniel Dudley, should read: MacSWEEN, George Burton William (in place of Westby, Norval Martin).

The errors occurred in the printing shop when final corrections were being made on the page proofs and were not caught in proof reading. Our apologies to the gentlemen involved and to the Minnesota State Board of Medical Examiners!

. . . now conveniently located for faster service

You need no longer risk driving through congested traffic to examine new equipment. In this new, modern store you will find complete stocks of instruments and supplies for the physician; model displays of hospital equipment of every type; and a comprehensive range of equipment, apparatus and supplies for the modern medical laboratory. We cordially invite you to visit us at your convenience, or call us for prompt emergency service. Free parking is provided adjacent to building. Telephone: LIncoln 7601.

Endowment of a research professorship in medicine, primarily in the field of high blood pressure, at the University of Minnesota, has been made possible through the receipt of a bequest from the estate of the late George S. Clark, prominent Georgetown, South Carolina, lumberman, who died in 1944. His early years were spent in this part of the country in association with the Carpenter lumber interests. After completing a project to reorganize one of the largest lumber mills in the South, Clark retired to Minneapolis in 1942. The bequest to the University, amounting to almost $400,000 in securities plus an interest in West Virginia coal lands, consists of the residue of the estate after payment of cash legacies to relatives, friends and Georgetown charities.

HOSPITAL NEWS

At a meeting of **St. Joseph's Hospital** staff, Saint Paul, held February 12, 1952, the hospital was presented with a plaque of merit by the Minnesota Public Health Association for being first to establish a routine x-ray of all patients admitted.

Dr. John Briggs presided at the meeting, and Dr. Herman Moersch of Rochester represented the Minnesota Public Health Association and made the presentation address. He related how, when it had been found that there was a higher incidence of tuberculosis among the nurses of St. Joseph's Hospital than in the general population, steps were taken by the Nurses Alumni Association of St. Joseph's, under the leadership of Miss Lucille McCoy, to raise the necessary funds to undertake the x-ray program.

Among those present were: Dr. A. J. Chesley, executive secretary of the Minnesota State Board of Health; Dr. M. E. Knapp, Father Flynn, Milton Rosen, A. A. O'Leary of the Blue Cross, Ray Higgins, executive secretary of the Minnesota Heart Association, and Dr. F. J. Hill, commissioner of health, Minneapolis Department of Health.

Elizabeth Kenny Institute, Minneapolis, has received a "full approval" rating from the American College of Surgeons in Chicago, according to Marvin L. Kline, executive director of the Sister Elizabeth Kenny Foundation.

Announcement of the "full approval" rating was made by Dr. Paul S. Ferguson, assistant director in charge of hospital standardization of the American College of Surgeons, following a survey in which the Institute scored 714 of a possible 785 points for a 91 per cent rating.

According to the report, Elizabeth Kenny Institute earned 578 of a possible 640 points in the "essential divisions" survey and 136 of a possible 145 points in the "complementary and service divisions."

BLUE CROSS-BLUE SHIELD

Recent study of sixty of the contracts of other Blue Shield plans in the continental United States has revealed interesting facts about the Minnesota Blue Shield contract. Questions are frequently raised about service and indemnity features of other plans. Premiums, waiting periods, and fees involved in other Blue Shield contracts provide a yardstick by which the liberality of the Minnesota program can be judged.

Without going into the uninteresting details of a statistical analysis it can be stated that about two-thirds of the plans analyzed are of the service type rather than indemnity. Indemnity plans usually provide a stipulated fee which might or might not constitute full payment for the service rendered. If the fee does not represent payment in full, the balance is collectible from the subscriber. Service plans usually include such related services as x-rays, endoscopy and anesthesia. Even among the 20 or more indemnity Blue Shield plans, many are attempting to convert to service contracts, since the latter are recognized as being more liberal from both the subscriber's and physician's viewpoint.

Another interesting comparison was that involving waiting periods for obstetrical cases, previously known conditions and tonsillectomies. The more liberal the policy, the shorter the waiting period. Thirteen of the plans analyzed excluded pre-existing conditions from contract coverage. Comparatively few plans had shorter waiting periods than those of Minnesota, and in 18 the waiting periods were longer.

Analysis and tabulation of premium rates of the various other plans presented some real difficulties. Only 39 of the service type of Blue Shield plans were reviewed regarding their premium rates. In general, it was found that the premium rates were higher for other Blue Shield contracts than for that of Minnesota, but this statement is particularly true regarding the family type of contract.

From these statements it is found that Minnesota Blue Shield, according to this analysis, (1) belongs with the majority of Blue Shield plans having the more liberal service type of contract, (2) compares very favorably with other Blue Shield plans in the length of waiting periods for confinement cases, tonsillectomies, and pre-existing conditions, and (3) has lower premium rates, especially for family contracts, than many of the other Blue Shield plans. Thus, in each of these features Minnesota Blue Shield's contract is more advantageous to both subscribers and doctors than many other Blue Shield contracts.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

AUDITORY TRAINING FOR THE DEAF. By Mary Wood Whitehurst and Edna K. Monsees. $3.12 postpaid. The Volta Bureau, 1537 35th Street N.W., Washington 7, D. C.

In recent years tremendous advances have been made in the education and communicative retraining of persons with impaired hearing. Modern hearing aids and improved educational methods have made oral communication less difficult.

Auditory training material for deaf and hard of hearing children and for hard of hearing adults has been published. It is believed, however, that this is the first book on the subject specificially written for the deaf adult.

Tests indicate that there are few totally deaf people. Many "deaf" persons have some residual hearing which can be trained and made to reinforce lipreading skill, thus making oral communication increasingly simple.

The material in this book has been prepared with three groups in mind: students in the schools for the deaf; alumni of schools for the deaf; others with severely impaired auditory acuity and discrimination.

The authors are trained teachers who have combined practical experience with modern scientific knowledge.

The lesson material has been tested and retested. There are thirty-eight lessons, each devoted to one or more speech sounds, progressing from the vowel sounds through the more difficult consonant sounds. Detailed instructions are provided, making it possible for the lessons to be used by teachers or by pupils for home study.

JANE WALKER'S BOOK OF ART LECTURES FOR LIP READING PRACTICE. $3.12 postpaid. The Volta Bureau, 1537 35th Street N.W., Washington 7, D. C.

Jane Walker's contribution to the teaching of lipreading is distinctive and unique. She was not only a skillful teacher of lipreading as a subject, but she was a person so well versed in art that she was able to combine those two subjects with great effectiveness. She was for many years a regularly scheduled lecturer in the Metropolitan Museum of Art—the only teacher of lipreading ever so scheduled. Her lectures were designed for and presented to people who read her lips. They were a source of great inspiration, for her appreciation of art extended far beyond the pictures themselves into a feeling for the artist, his life, and his times.

Along with the book goes a package of prints of some of the pictures by artists discussed in the lectures. Two of the prints were secured by courtesy of the Metropolitan Museum, one has been donated by the *Saturday*

UNTOWARD REACTIONS OF CORTISONE AND ACTH. By Vincent J. Derbes, M.D., F.A.C.P., Associate Professor of Medicine, Tulane University of Louisiana School of Medicine; Head of Department of Allergy, Ochsner Clinic; Visiting Physician, Charity Hospital of Louisiana at New Orleans; and Staff Member, Foundation Hospital, New Orleans, Louisiana; and Thomas E. Weiss, M.D., Instructor in Medicine, Tulane University of Louisiana School of Medicine; Member of Department of Medicine, Ochsner Clinic; Visiting Physician, Charity Hospital of Louisiana at New Orleans; and Staff Member, Foundation Hospital, New Orleans, Louisiana. 77 pages. Price $2.25. Springfield, Ill.: Charles C Thomas, 1951.

In only seventy-seven pages of relatively easy reading, the authors have concisely presented a summary of the untoward reactions of ACTH and cortisone. From this book one can obtain clear and quite thorough information regarding the dangers and pitfalls of cortisone and ACTH therapy. The basic physiology of the two compounds is brought out briefly but well. A short but well-selected bibliography is appended to the book.

This book represents a brief résumé of the clinical side effects of ACTH and cortisone.

J. F. Alden, Jr., M.D.

MINNEAPOLIS SURGICAL SOCIETY

(Continued from Page 246)

was done and the tumor tissue removed. This was followed by further x-ray therapy which was accompanied by considerable improvement. However, in another six months she had very extensive abdominal metastases and eventually she died. I assume others of you have had similar experiences, particularly those of you who are more in contact with children's surgery. With this in mind, I would like to call upon Dr. T. Chisholm to discuss this paper.

Dr. T. Chisholm: I would like to express my appreciation to Dr. State's review of this subject. My first comment would be on the recoverability of children who have neuroblastoma. This was formerly thought to be a fatal disease. Metastases have nearly always been quite extensive. These should not deter us from removing the tumor and going after the metastases. I recall one youngster who had a large neuroblastoma in the left adrenal, which on being explored transperitoneally was found to have multiple metastases to the liver. The adrenal was removed, and the metastases were given deep x-ray therapy. The child is still alive seven years after surgery. Another example is a youngster who had a right adrenal neuroblastoma which was removed transperitoneally and was thought to be all right. The child came back with a metastasis to the seventh rib. This was treated by surgical excision and x-ray therapy. The child is still alive seven years later. Too often we are too late and there are studded metastases but those with very few metastases warrant treatment.

The second comment I would like to make is on disorders of nerve cells of the ganglia. Both neuroblastomas and ganglio-neuromas may arise up and down the sympathetic chain. Again, I recall a youngster who had a malignant neuroblastoma. The tumor was partially removed and given extensive therapy. There remained a local nodule palpable in the abdomen which was subsequently removed, and the child was cured.

My third comment has reference to tumors of the medulla. Many, on surgery, are found to be malignant carcinoma of the adrenal cortex, mon-functioning in type.

My next comment is in reference to pheochromocytoma which is more common in adults. From my own limited experience, I would say one need not be fearful of giving adrenalin intravenously in enormous amounts at the time the tumor is removed.

My last comment is with reference to abnormal virilism of females. This is a "no-man's-land," extremely treacherous. But whether boys or girls, I am sure we are just beginning to explore the field. Again, I wish to say how thoroughly I enjoyed Dr. State's presentation.

In infant formulas...

proper

caloric

distribution

calls for

adequate added carbohydrate

Frequent mention in authoritative pediatric literature supports the classic caloric distribution of 15% protein, 35% fat and 50% carbohydrate for infant formulas.

This assures ample protein for development of sound tissue structure. And it supplies *adequate carbohydrate* to spare protein for its essential functions, meet energy needs, promote good fat metabolism and maintain water balance.

This classic caloric distribution is conveniently represented by 1 part evaporated milk and 2 parts water with 5 per cent added carbohydrate—roughly 1 tablespoon of Dextri-Maltose to each 5 ounces of formula.

For over 40 years, milk and Dextri-Maltose formulas with these approximate proportions have enjoyed consistent clinical success.

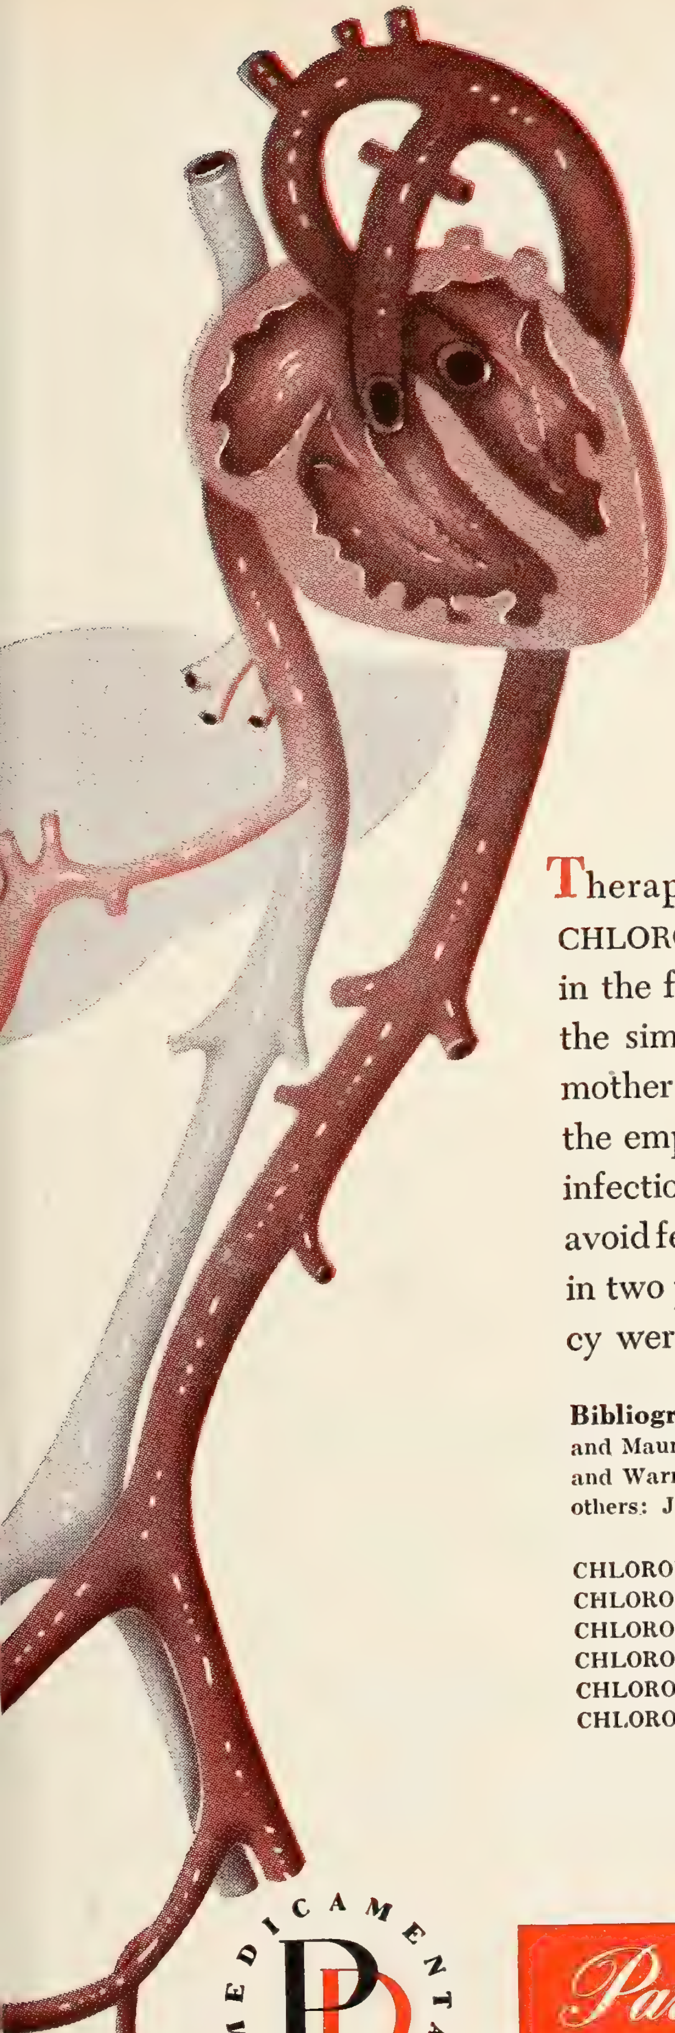
MEAD JOHNSON & CO.
EVANSVILLE 21, IND., U.S.A.



Therapeutic concentrations of well tolerated CHLOROMYCETIN (chloramphenicol, Parke-Davis) in the fetal blood stream are easily obtainable "by the simple oral administration of the drug to the mother."[2] Investigators have suggested, therefore, the empiric use of CHLOROMYCETIN in such virus infections as atypical pneumonia, in an attempt to avoid fetal damage.[3] Results with CHLOROMYCETIN in two patients with typhoid fever during pregnancy were reported recently as "quite satisfactory."[1]

Bibliography: (1) Stevenson, C. S.; Glazko, A. J.; Gillespie, E. C., and Maunder, J. B.: J.A.M.A. *146*:1190 (July 28) 1951. (2) Scott, W. C., and Warner, R. F.: J.A.M.A. *142*:1331 (April 29) 1950. (3) Ross, S., and others: J.A.M.A. *142*:1331 (April 29) 1950.

WISHFUL THINKING

Those of you who haven't yet paused in your busy day to provide for adequate income protection, are guilty of wishful thinking. You are hoping that the law of averages will pass you by. Most of us know that you can't depend upon a four-leaf clover.

This Special Disability Policy offers more protection per dollar than any other contract on the market.

Our counsel is to stop depending upon a four-leaf clover. Call or write this office NOW—the result will be much safer.

control companion to ACTH and CORTISONE

“In clinical practice it is clearly wise to test the urine of both diabetic and non-diabetic patients for sugar at intervals during administration of cortisone or ACTH and to carry out appropriate investigations and treatment if glycosuria occurs. Particular caution is necessary for diabetic patients.”

Sprague, R. G.: Cortisone and ACTH, Am. J. Med. *10*:567, 1951.

To avoid such clinical surprises and simplify clinical control, ACTH and cortisone therapy is profitably *preceded, accompanied* and *followed* by routine testing for urine-sugar. *Clinitest* Reagent Tablets provide a rapid, reliable and convenient method—easily used by both physician and patient.

CLINITEST *for detection of urine-sugar*

BRAND • REG. U. S. PAT. OFF.

REAGENT TABLETS

You can assure regular, reliable urine-sugar analyses by prescribing the Universal Model Set (No. 2155). Available at all pharmacies at $1.50.

STILL
setting the fashion trend

right through the menopause

...on oral estrogen therapy that imparts

no odor,

no taste,

no aftertaste

Convince her that the climacteric is not the be-all and end-all of her life and you solve, perhaps, her most serious problem. Then, prescribe SULESTREX. As effective estrogen therapy as science has yet created, SULESTREX will conveniently, esthetically and rapidly end the physical symptoms. Odorless and tasteless in small compressed tablets, SULESTREX will never cloud her breath or perspiration.

Following a study of 58 standardized menopausal patients, in which all attained complete symptomatic relief, Perloff[1] termed SULESTREX a "potent and effective oral estrogen with an extremely low incidence of nausea." Another recent report on a controlled study by Reich and associates[2] states that "all patients noted a marked sense of well-being, and commented on their ability to resume normal activity with amazing vigor."

Now available in three potencies for your prescribing convenience—0.75-, 1.5- and 3-mg. grooved tablets—SULESTREX is stocked by pharmacies everywhere. Try this esthetic therapy soon or write for complete information. Abbott Laboratories, North Chicago, Illinois. Abbott

Where does the MAICO MAN fit in?

Wherever men of medicine look to electro-acoustic science, you'll find the Maico Man. At work—*behind the scenes!*

Silently, unobtrusively—he answers your call when the very young patient needs special auditory training equipment for use in the home; when you must be assured of integrity in the custom-fitting of a precision hearing aid to meet the individual needs of your patient; when your practice demands the most exacting in advanced auditory testing and training equipment.

He stands ready when it's time for your Maico Precision Audiometer to go back to the Maico Laboratories for periodic recalibration and inspection. He makes all arrangements; he frees you from all detail.

His is a career of service to hearing science. His services—*as available as your office telephone.*

DRYCO

A dehydrated milk-food
LOW in fat and carbohydrates
HIGH in protein and minerals

Confirmation of the need of prematures for the easily-digested Dryco formula is found in the study by Gordon.* For more than three decades, this low-fat, high-protein milk food has meant minimum digestive derangement from fat . . . plus the valuable tissue-building benefits of protein. For the premature, these are important food considerations. Dryco's easy digestibility, due to its soft flocculent curd of small particle size, further enhances its choice for premature feeding. Dryco is a spray-dried half whole, half skim-milk mixture, vitamin fortified with vitamins A and D. Only supplementary vitamin C need be added. Dryco is readily reconstituted in cold or warm water and permits a wide range of formula flexibility to meet the varying nutritional requirements of the premature.

Additional data and samples will be mailed on request.

*Gordon, Harry H.: Feeding of Premature Infants, American Journal of Diseases of Children 73:713 (June) 1947.

DRYCO® *Each tablespoonful supplies 31½ calories.*
Frequently used for supplemental feedings.
Available at pharmacies in 1 and 2½ lb. cans.

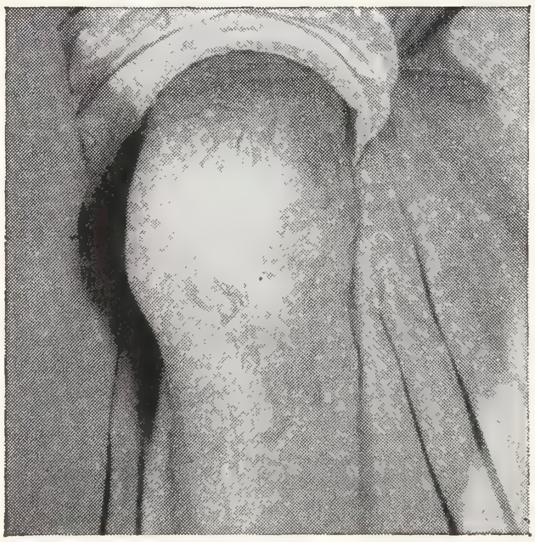
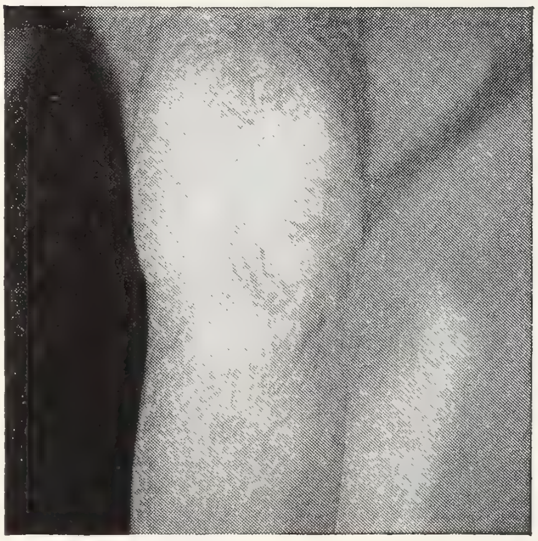
SCHERING

Cortone®

Can be used Safely in the Prolonged Control of Rheumatoid Arthritis



BEFORE TREATMENT:
Periarticular swelling and hydrarthrosis



AFTER TREATMENT:
Diminution of pain, increased mobility, and visibly decreased effusion and swelling

Rehabilitation Achieved Through Conservative Dosage

Management in Everyday Practice

The use of simple laboratory tests (sedimentation rates, urinalyses, blood counts, blood pressure, and frequent weight recordings), individualized adjustment of dosage, and careful clinical observation will permit most patients to benefit materially . . . without fear of undesired effects.

Effective Antirheumatic Response

Effective antirheumatic response was achieved in all 100 patients in a long-term study at the Mayo Clinic. More than 50 of these arthritics were maintained on 50 mg. or less daily. In no case was it necessary to withdraw the hormone.

Ward, L. E., Slocumb, C. H., Polley, H. F., Lowman, E. W., and Hench, P. S.: *Proc. Staff Mtgs., Mayo Clinic* 26: 361, September 26, 1951.

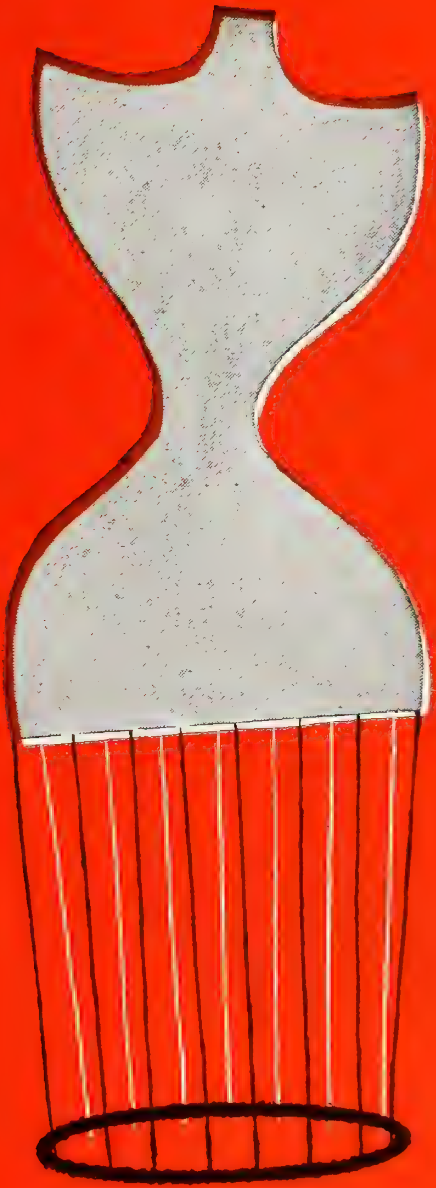
tailored to the moment



Whenever capillary bleeding becomes a hazard in surgery

Gelfoam*

BRAND OF ABSORBABLE GELATIN SPONGE

is tailored to fit the situation.

Gelfoam may be speedily cut to shape and pressed against oozing capillary surfaces, where it rapidly *absorbs* up to 45 times its own weight in blood. Left *in situ,* Gelfoam is completely *absorbed* in 20 to 45 days with virtually no cellular reaction.

Gelfoam is supplied in a variety of convenient sizes, including a sterile surgical sponge, dental pack, prostatectomy cone, and biopsy sponge.

THE RESULT OF MODERN RESEARCH

Put an end to overnight soaking by using KLER-RO. In just ten minutes crusted coatings of blood and contamination are readily dissolved without affecting the sharp edges or points of surgical instruments. KLER-RO cleans instruments of the most intricate design—penetrates hard to reach parts with ease and efficiency.

Surgical linens are saved from quick discard or transformation into autoclaving wraps. Smock, apron and gown emerge from the KLER-RO solution with all evidence of blood stains removed. KLER-RO is economical. A single 2 lb. can gives you 42 gallons of full strength detergent solution.

Order KLER-RO today, or send for your trial sample. Test KLER-RO on your hardest cleaning problems and you will see why we say, "They'll Come Clean With KLER-RO."

from among all antibiotics, Surgeons often choose

AUREOMYCIN

Hydrochloride Crystalline

because

Aureomycin exhibits little tendency to favor the development of resistant strains of bacteria.

Aureomycin rapidly penetrates all tissues of the body, particularly those of the gastrointestinal tract, and it has been found useful prophylactically in surgery of the tract.

Aureomycin has been reported to be effective against susceptible organisms in—

- Abscess
- Actinomycosis
- Carbuncles
- Cellulitis
- Empyema
- Furunculosis
- Gallbladder Infection
- Human Bites
- Infected Burns
- Intestinal Perforation
- Peritonitis
- Soft Tissue Infection
- Ulcerative Colitis
- Vascular Infection
- Wound Infection

Throughout the world, as in the United States, aureomycin is recognized as a broad-spectrum antibiotic of established effectiveness.

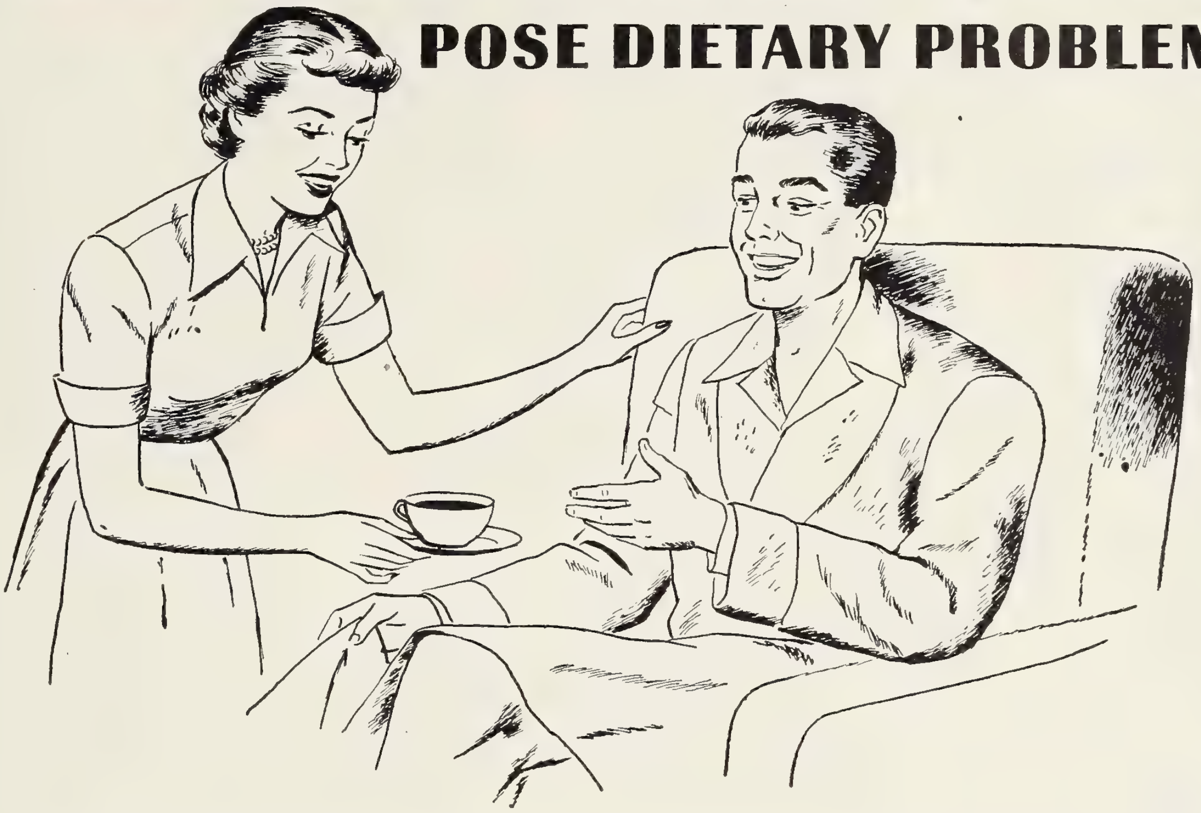
When Functional Derangements POSE DIETARY PROBLEMS



In the interest of maintaining good nutrition in the patient, many functional derangements of the gastrointestinal tract make the use of a well rounded dietary supplement, such as Ovaltine in milk, highly advantageous. Among such functional derangements more commonly encountered are nausea, anorexia, gastritis, diarrhea, dysentery, enteritis, and colitis.

In these conditions, Ovaltine in milk is particularly useful, not only because of its easy digestibility but also because of its blandness and its high nutrient content. It offers the opportunity of providing a balanced fare of essential nutrients without mechanical irritation or excessive digestive demands. Hence it qualifies especially when customarily eaten foods are contraindicated and a nutritious bland diet is required.

The wealth of nutrients supplied by three glassfuls of Ovaltine in milk is outlined in the table below.

THE WANDER COMPANY, 360 N. MICHIGAN AVE., CHICAGO 1, ILL.

OVALTINE
OVALTINE

Doctor Harris hooks a big one

Zing-g-g-g! The sweet whine of the reel. The surging pull. Steady now. Slowly. Oh, oh! Let him run. Keep it tight . . . . At last the great glistening prize lies thrashing on the deck, only slightly more exhausted but certainly less pleased than Dr. Harris, who leans back in his chair to let the warm sun soothe his closed eyes. His mind flits back to his practice and to Mrs. Ames, whose tuberculosis is still being successfully treated with an anti-infective—during his much-needed holiday. It occurs to him that back in '39, the last time he took a real vacation, he couldn't have left a tuberculous patient behind with the same mutually comforting assurance of continuing recovery. "Come to think of it, I wouldn't enjoy this trip half so much if those drug people hadn't teamed up with the investigators who discovered that . . .

Lilly

. . . the earth contains medicine

Following the initial discovery of streptomycin in the soil, extensive laboratory and clinical studies were instituted by the pharmaceutical industry in order to establish the usefulness of this antibiotic.

Eli Lilly and Company continues a painstaking quest for even more widely useful or more effective substances. Although the present trial-and-error approach is laborious, it is gradually being accelerated by a new method of biochemical investigation aided by a rapidly developing knowledge of physiology and biochemistry.

CERVICAL SMEARS IN THE DETECTION OF PRECLINICAL CARCINOMA

DAVID C. DAHLIN, M.D., ELIZABETH MUSSEY, M.D., and
MALCOLM B. DOCKERTY, M.D.

Rochester, Minnesota

THE PURPOSE of this presentation is to emphasize certain lines of endeavor in the diagnosis of carcinoma of the uterine cervix—a type of carcinoma which ranks second only to carcinoma of the breast as a cause of death from malignant disease among females. The seriousness and the insidiousness of the condition were recognized a century and a half ago when Baillie wrote, "This disease (ulcer of the cervix) is certainly as formidable as cancer because it terminates fatally, but its progress is different from that of cancer in any other part of the body. There is no enlargement of the uterus, and ulceration continues until the greater part of the uterus is destroyed. . . ."

Surgical attacks on the disease, as typified by operations such as Wertheim hysterectomy, gave promising results chiefly in treatment of early lesions, which unfortunately comprised the minority; the advent of treatment with radium and roentgen rays provided substantially additional salvage; in the hands of a few experienced investigators "combined" techniques, in which surgery and irradiation were used, received merited acclaim. Yet, by the late nineteen thirties, carcinoma of the cervix still claimed the lives of 60 per cent of its victims and it was obvious that some other avenue of approach to the problem was necessary to improve the over-all picture. Such an approach was afforded by applying to cervical carcinoma two novel concepts regarding its very earliest recognizable stages—stages often devoid of clinical symptoms.

Nearly thirty years ago, and despite bitter criticism by many contemporary pathologists, MacCarty stressed the significance, in the diagnosis of malignancy, of cytologic features rather than histologic structure as disclosed under low power magnification. He decried procrastination until spread had made the diagnosis obvious and the outcome hopeless. In 1932, Broders described, and gave the name to, carcinoma *in situ* of the cervix, breast, skin, colon and larynx. He stated, "the microscopist must take into consideration the character of the epithelial cells above everything else" in diagnosing malignancy.

Carcinoma *in situ* is a cytologically malignant lesion that has not broken through the normal barrier that separates epithelium from underlying stroma. In the cervix this early change may, and often does, involve by a process of creeping replacement, so to speak, the mucous glands in the area of the external os. Such involvement of glands does not imply invasion with the resultant possibility of metastasis but it often constitutes a problem of interpretation since practically all carcinomas of the cervix begin in the squamous epithelium at the squamocolumnar junctional zone.

The second important concept, developed by Papanicolaou, embodied the principle that carcinoma, growing on a free surface such as that of the cervix, exfoliated certain of its cellular elements which could be identified as such by cytologic studies of secretions, smears and scrapings from the part. He demonstrated clearly that the material thus shed from the surfaces of cervical carcinomas *in situ* was just as diagnostic

---

From the Division of Surgical Pathology and Sections of Obstetrics and Gynecology, Mayo Clinic.

as that derived from advanced growths, and it was oftentimes easier of interpretation. Carcinomas *in situ,* discovered by this cytologic smear technique, were attended by a rate of cure approaching 100 per cent. The present study was conducted in an effort to evaluate our own experience in employing cervical smears as the principal means of detecting early carcinoma of the cervix.

Material

The Sections of Obstetrics and Gynecology at the Mayo Clinic in co-operation with that part of the Division of Surgical Pathology which is situated at St. Mary's Hospital, began to evaluate the cervical smear in 1948. Since August 1, 1950, in the Sections of Obstetrics and Gynecology at the clinic, smears have been obtained almost routinely on new and referred patients, with the exception of new obstetrical patients and women less than thirty years of age whose cervices apparently were normal. As a result, more than 10,000 smears, one from each patient, have been examined by means of the newer cytologic techniques. We have reviewed the records of ninety-two of the first 10,000 patients screened in this manner. These were subsequently proved to have carcinoma of the cervix, although their cervices did not initially exhibit lesions which were believed by the examining physician to be carcinomas.

Clinical Data

The ages of the patients in this group of ninety-two ranged from twenty-five to seventy-six years and were distributed by five-year intervals in Table I. It is apparent that the spread of patients is fairly even between the ages of thirty-five and fifty-five years and that there is a smaller but clearly important group less than thirty-five years of age.

TABLE I.
MALIGNANT CELLS IN SMEARS OF UTERINE CERVIX

55-59	6
60-64	2
65-69	3
over 70	1

The average age of seventy-three patients whose cervical carcinomas proved to be *in situ* was 42.1 years, with a range of twenty-five to sixty-nine years. In the small series of eleven patients with early invasive carcinoma, the average age was 47.8 years with a range of thirty-four to seventy-six years. These figures are essentially in agreement with those quoted by Jones, Galvin and TeLinde, who collected from the literature average ages of 37.1, 36.6 and 38 years for carcinoma *in situ* and who cited forty-eight years as the average age of patients with invasive carcinoma. The stage of the lesions of the remaining eight patients was undetermined for reasons to be pointed out.

Of the ninety-two patients, eighty-one were married, four were widowed, six were divorced, and only one was single. Twelve of the patients had never been pregnant, four had had one or more pregnancies that had resulted in abortion, while the remaining seventy-six had had at least one full-term pregnancy.

The complaints with which these patients sought medical advice were varied. In the majority of cases, there was no relation between the predominant symptom and the cervical carcinoma which ultimately was discovered. Thus, only seventeen patients presented themselves primarily because of gynecologic problems, while sixty-three patients made complaints which were not gynecologic in nature and twelve other individuals requested general examination but made no specific initial complaint. Most of the last group were in Rochester only to accompany a friend or relative.

An attempt was made to determine how many of the ninety-two patients had symptoms of a gynecologic nature which might have provided a clue to the presence of a malignant lesion of the cervix. Forty-eight patients had no recorded symptoms of gynecologic disease. Thirteen patients complained of gynecologic conditions, such as infertility, which were considered irrelevant to this study. From the remaining thirty-one patients were elicited histories of abnormal discharge or bleeding. This symptom did not appear to be the result of the cervical carcinomas of fifteen of these thirty-one patients but the unusual bleeding or discharge of the other sixteen patients at least suggested the presence of a neoplasm of the genital tract. Ten of the ninety-two patients previously had undergone subtotal hysterectomy. In the histories of eight patients was recorded the fact that the cervix previously had been subjected to cauterization. In three of these eight cases this procedure had been carried out at the Mayo Clinic and in five cases it had been performed elsewhere.

The cervices of nineteen patients of the ninety-two were said, on inspection, to be normal. These patients included all post-menopausal women whose cervices were merely described as "senile." Vaginal stenosis prevented inspection of the cervices of two patients at the time when the smear was obtained. The cervical lesions of twenty-four patients were said to be minimal and did not appear significant. The cervices of thirty-six patients exhibited lesions which appeared to be clinically significant enough to merit the designation "angry," "friable," "denuded," "rough," "granular" or "reddened," and for which treatment by cauterization was recommended or carried out. In only eleven instances did the description of the cervix suggest that a suspicion of malignancy had been aroused in the mind of the examiner.

Although the relationship between leukoplakia of the lip or of the vulva and the subsequent appearance of squamous cell epithelioma has long been accepted, it has not been universally recognized that leukoplakia of the cervix may be a precarcinomatous lesion. In this series of cases leukoplakia was noted four times by the clinician only. In one case leukoplakia was a pathologic diagnosis only and in three additional cases the presence of leukoplakia was noted by both the clinician and the pathologist. Thus, in eight of ninety-two cases, or more than 8 per cent, leukoplakia was associated with invasive or pre-invasive carcinoma of the cervix.

In a further attempt to learn the value of the smear method in finding unsuspected cervical carcinoma, the patients were divided into groups in accordance with the indications for biopsy. It was found that, in forty-nine cases, the appearance of the cervix alone justified the securing of a specimen for biopsy. In one case biopsy was taken solely because of the patient's fear of carcinoma and her request that it be ruled out. In thirty-eight cases a smear only was taken at the time of the first examination, the specimen for biopsy being secured later as a result of the positive report on the smear. In one case biopsy was not performed, and in three others the procedure was carried out in the patient's home city.

An attempt was made to determine the final stage of extension of each lesion which was detected as a result of smear or biopsy. Seventy-three patients were classified as having squamous cell epithelioma of the cervix Stage 0;* that is, carcinoma *in situ.* The carcinomas of eight patients were of Stage 1. However, at least four of the eight lesions were placed in this category *after* conization of the cervical canal or other procedures had disclosed what the surgical pathologist termed "early" or "very early" infiltration. In one instance of the eight, a diagnosis of epidermoid carcinoma, Grade 3, with minimal infiltration, was made on a specimen taken for biopsy in the office. At subsequent hysterectomy in this case, only carcinoma *in situ* was found. In three cases the stage was listed as two but in none of these cases was it possible to secure pathologic verification of extension such as is designated by this stage, because the patients were treated with irradiation. One patient had a concealed adenocarcinoma of the cervix and endocervix. In seven cases biopsy either was not carried out or final biopsy was done elsewhere and the anatomic extent of the lesion could not be determined with accuracy. It is difficult to believe that a carcinoma of the cervix, Stage 2, could be unrecognized or unsuspected at the time that the initial examination was made, but in at least one of the three cases in which the lesions were listed as being of Stage 2, a correct diagnosis appears to have been made only because a smear was taken.

Although a consideration of treatment does not properly belong in a presentation dealing only with the cervical smear as a diagnostic technique, nonetheless it might be of interest to point out briefly the final disposition of the ninety-two patients included in this series. Of the seventy-three patients whose lesions were proved to be of Stage 0, forty were subjected to vaginal hysterectomy, fourteen to total abdominal hysterectomy, one to radical hysterectomy, eight to excision of

---

*Added to International Classification of Cervical Cancer.

TABLE II.

INITIAL SMEAR IN EARLY CERVICAL CARCINOMA
92 Cases

Group		Cases
Number	Significance	
5	malignant	59
4	probably malignant	17
3	suspicious	12
2	probably benign	1
1	negative	3

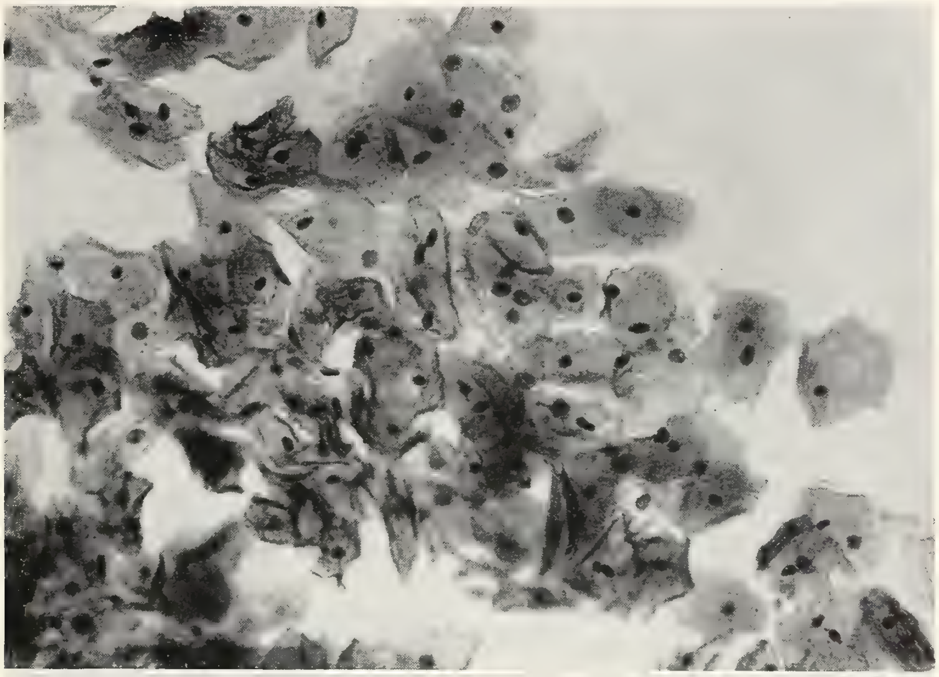
the cervical stump, four to insertion of radium and one to radium therapy followed by surgical operation. Five patients who received a provisional diagnosis of carcinoma "probably" *in situ* were untreated here for various reasons. Of these, one was known to have undergone panhysterectomy elsewhere. Of the eight patients whose lesions were of Stage 1, four underwent operation only, three received irradiation only and one was treated with irradiation and surgical operation. All three of the patients whose carcinomas were of Stage 2, received irradiation, and the one patient with adenocarcinoma of the cervix and endocervix was treated by total abdominal hysterectomy. Of the seven remaining patients, the final stage of whose carcinomas was unknown, five were treated by their home physicians and two received no treatment of which we have a record.

An effort was made to ascertain whether preoperative biopsy or cauterization destroyed any of the lesions and we centered attention on sixty-four patients whose carcinomas *in situ* were treated surgically at the clinic. Data suitable for this type of analysis were furnished by fifty-three records. Complete study of the cervices of these fifty-three patients revealed residual carcinoma *in situ* in thirty-eight instances only. Fourteen of these thirty-eight had undergone cauterization following biopsy in the office. Of the group of fifty-three patients, there were fifteen who exhibited no residual carcinoma at the time of surgical exploration; of these, seven had undergone biopsy only and eight, biopsy followed by cauterization. It is apparent, therefore, that both cauterization and simple biopsy of the uterine cervix can eradicate completely a carcinoma *in situ* but the proof of total destruction of the lesion can be obtained only at the time of examination in the laboratory of the completely excised cervical epithelium, whether obtained by cervical amputation, conization or hysterectomy.

In a few cases, either the initial smear or the biopsy failed to reveal the carcinoma which later was found to be present. In two cases, the result of the initial smear was negative while the biopsy revealed, in each instance, squamous cell epithelioma *in situ*. In one case, a negative smear was obtained but, on the following day smear and biopsy each gave a positive result. In three cases, the initial smear gave a positive result but the biopsy was not confirmatory. In one of these three cases, two smears were classified as of Group 3 and Group 4 (Table II) respectively. On biopsy, chronic cervicitis was reported. Complete search of the excised cervical stump yielded a minute squamous cell epithelioma, Grade 2, *in situ*. In the second case of the three, biopsy was interpreted as giving evidence of chronic cervicitis with leukoplakia and "borderline" neoplastic changes. Accordingly, another smear and a second specimen were obtained. In the former suspicious cells were seen but the tissue was the site of chronic cervicitis only. However, at vaginal hysterectomy a definite diagnosis of squamous cell epithelioma *in situ* was established. Concerning the third patient of the three, the smear disclosed the presence of malignant cells and the report of biopsy was "inflammatory tissue." One month later biopsy of the cervix and dilatation and curettage were performed elsewhere, but carcinoma was not found. Again, one year later, postmenopausal bleeding developed. Two months after the onset of bleeding, and approximately fifteen months after the positive smear had been obtained, biopsy yielded a specimen which was found to contain squamous cell epithelioma, Grade 3.

Pathologic Features

Detailed discussion of the cytologic features of cervical smears for diagnosis of malignancy lies beyond the scope of this presentation. Suffice it to say that the critical criteria of large nuclear size, heavy nuclear membranes, irregular nuclear outline, hyperchromatism and so forth are matters of general acceptance.[4,6] Figures 1 through 4 may be regarded as typical end points of a range of cellular alterations correlating cytologic with histologic interpretation. In the study of smears the line which separates hyperplasia from malignant neoplasia is not as sharp as its histologic counterpart. Accordingly we have, like others, found it advisable to retain five classifications (Table II) in reporting results of our analysis. With experience, the proportion of equivocal interpretations has been materially reduced but the number of carcinomas detected by repeating smears and performing biopsy in the cases concerned in this report has promoted pathologic humility and discouraged dogmatism.



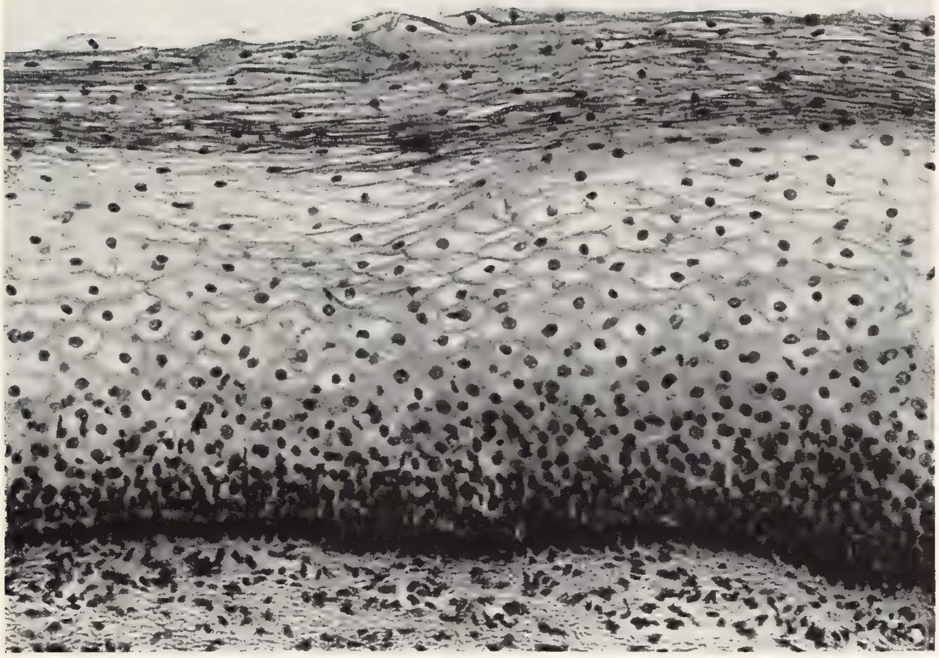


Fig. 1. Normal adult squamous cells from the cervix. Note the small nuclei and voluminous cytoplasm (Papanicolaou stain × 200).

Fig. 2. Normal squamous epithelium of the cervix with progressive maturation toward the surface (polychrome methylene blue stain of fresh frozen section × 145).

Of 5,500 cases studied by the method just mentioned between January 1 and September 6, 1951, we requested additional studies on fifteen patients because of false "suspicious" reports. Subsequent smears or biopsies, either or both, decided the issue. In two additional cases so-called false positive smears appeared not to have a basis in carcinoma. In the last three months of the period there were only three false suspicious smears and no false positives. Of the three false negative interpretations in the entire series, one should have been considered unsatisfactory owing to an excess of pus in the smear. In the others, one or two malignant cells had escaped detection on the original analysis.

While the fruitless biopsies made necessary by the aforementioned "blunders" must be accepted as evidence that smears represent a less efficient method than was hoped for, still results have been most encouraging. During the same period in 1951 that has been mentioned, study of cervical smears was responsible for, or aided materially in, the diagnosis of no less than fifty-two potentially curable carcinomas. Representing, for the most part, invisible and nonsymptomatic growths, the group comprised perhaps 30 per cent of all cervical malignancies encountered at the clinic over the same span of time. Differences in the outcome in the two groups, carcinomas *in situ* and infiltrating carcinomas have been previously emphasized.

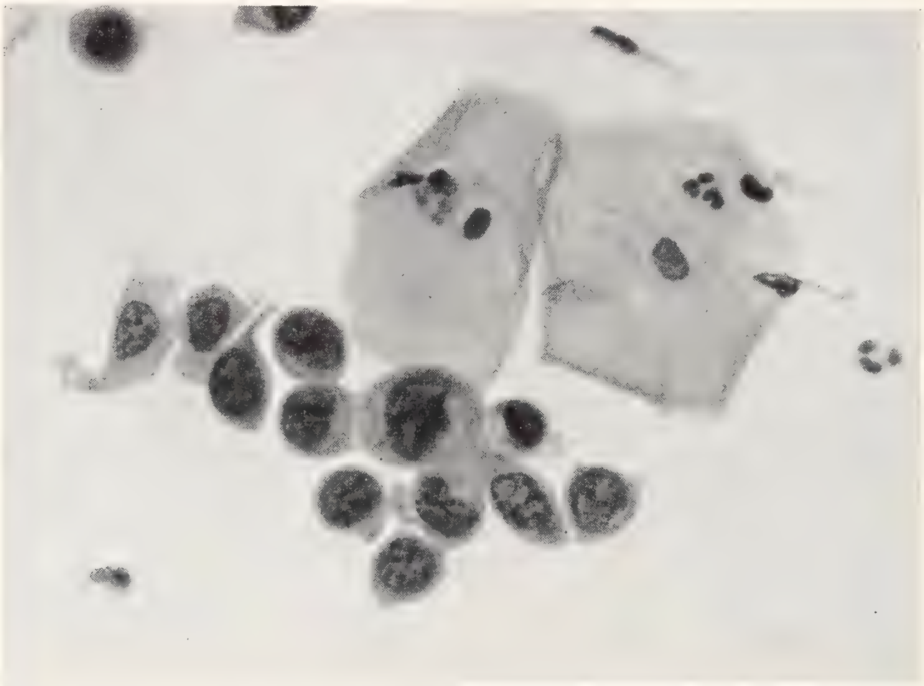

Fig. 3. A cluster of malignant and two benign cells. Note the nuclear pleomorphism, hyperchromatism and anisocytosis (hematoxylin and eosin×475).

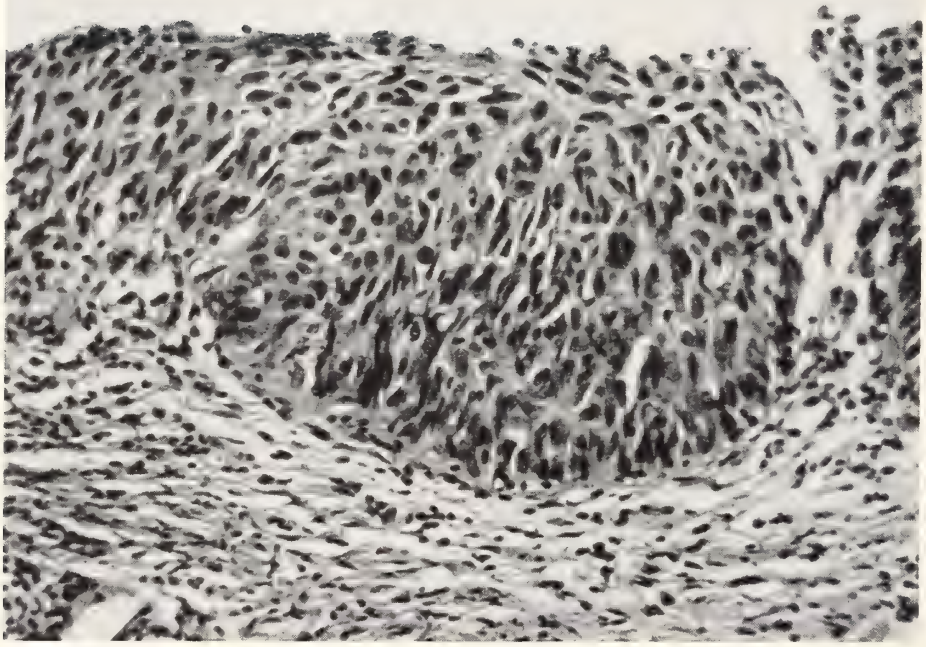

Fig. 4. The squamous cell carcinoma *in situ,* Grade 3, from which the malignant cells in Figure 3 were shed (hematoxylin and eosin×235).

In the detection of carcinoma of the uterine fundus, smears have not proved efficacious in our experience. One cannot reach the surface of the growth to secure material and cervical stenosis often prevents escape of the malignant cells into the vaginal pool of secretions. Moreover, the cells observed following exfoliation from fundal growths are so well differentiated, and so unlike those of cervical carcinoma, that the interpretation may be erroneous. In addition to this, the relative rarity of the lesion (fundal carcinomas are one fifth as common as cervical carcinomas), its early production of bleeding, its accessibility to the curet and its comparative curability, were factors which have influenced us to concentrate our efforts in the detection of early carcinoma of the cervix.

For those interested in planning a "screening" program for detection of carcinoma based on cytology of smears, certain other of our observations might be useful.

We do not intend that the smear should replace the biopsy. If the patient has an obvious carcinoma of the cervix, routine diagnostic biopsy is the proper procedure. Under these circumstances the smear serves no useful purpose except as a means to acquire experience in the reading of "positives." Biopsy always should be employed likewise to verify all positive and equivocal smears before any definitive treatment is undertaken. It is imperative that, during the procedure of "verification," except when the specimen of tissue includes a completely conized cervical canal plus the squamocolumnar junction, the postbiopsy cautery be applied with utmost reluctance. All too often the bona fide evidence of carcinoma of the cervix *in situ* has ascended in the smoke of such burnt offerings. This practice, like performance of dilatation and curettage prior to cervical biopsy in certain of our problem cases, has done injustice to the smear program.

Our technique in the taking of material for smears, and in the preparation and analysis of them, is similar to that followed by others, with certain minor modifications. Smears secured by scraping or wiping the squamocolumnar junctional area of the cervix seemed to give a higher concentration of cells than did swabbings from the lower vaginal pool.

In the earlier phases of our work, two or more smears were obtained in each case and smears were taken from many overt carcinomas, chiefly that we might gain experience. The limiting factor in the number of cases that can be screened is the time required for the necessarily thorough scanning of the slides. Hoping to learn that a single slide per case would be adequate, we reviewed the material from our first 100 positives. Malignant cells were present on each and all of the slides. Our current practice is to prepare one such slide of material obtained from each patient.

We adopted the standard hematoxylin (Harris) and eosin stain after a preliminary trial of the Papanicolaou technique. We believe that for the detection of malignant cells, hematoxylin and eosin is at least as good as the other more complex stain. The former has the added advantage of familiarity. Ninety-five per cent alcohol has proved to be an excellent fixative for the smears and it has reduced the fire hazard associated with the ether-alcohol mixture formerly employed.

It is impracticable for the pathologist to attempt the screening of a large number of cervical smears without the assistance of trained technicians. The troublesome and positive smears, as well as the biopsy material, must be analyzed by a competent pathologist. However, a well-trained technician is capable of handling the negative smears from a series of 5,000 women annually.

Discussion

Granted that the techniques we employed are highly valuable for the detection of carcinoma of the cervix *in situ,* one might now well inquire whether, and following what interval of time, these cytologic changes are succeeded by the development of clinical carcinoma in the organ. Jones, Galvin and TeLinde recently have summarized the available literature on this important issue. They found documentary evidence concerning 40 patients whose cervical carcinomas *in situ* had, under observation or by accident, been allowed to progress, and which eventually did progress into manifestly invasive lesions.

An average difference in age of approximately ten years between patients who exhibit carcinoma *in situ* and overt carcinoma of the cervix indicates that the lesion remains intraepithelial during this interval. The seven cases reviewed by Jones, Galvin and TeLinde support such a concept; these patients had carcinoma that remained *in situ* for periods ranging from one and a half to eight years. Galvin and co-workers are reported by Jones, Galvin and TeLinde to have reviewed material obtained long before at biopsy performed on thirteen patients who subsequently had clinical carcinoma of the cervix. In eleven instances the changes currently recognized as carcinoma *in situ* were found on review of the tissue originally removed. One exhibited basal cell hyperactivity and, in the remaining case, the specimen had been denuded of epithelium. Our own series provided circumstantial evidence that carcinoma *in situ* and invasive carcinoma of the cervix are one and the same process. Only one of our ninety-two patients had not been married. The rarity of invasive cervical carcinoma among unmarried women is well known.

There are, on the other hand, nine examples recorded in the literature wherein carcinoma *in situ* apparently has reverted to normal. In none is the possibility excluded that the biopsy, especially if followed by cauterization for hemostasis, did not destroy all of the original lesion.

Clinically applied, present-day importance of cervical smears can be illustrated by citing the experience of our Sections of Obstetrics and Gynecology during the first eight months of 1951. Excluding obstetrical patients, 7,960 new patients were examined and, of these, cervical smears were made of 5,459. The latter number of cases compose part of the series of 10,000 with which this paper is concerned. Fifty-two, or approximately 1 per cent, of the 5,459 patients proved to be shedding malignant cells from clinically undetected carcinoma of the cervix. Smears from only two patients, or approximately one in 2,700, were false negatives which might have led to the patient's dismissal had not detection of early carcinoma been made by other means.

It might be argued that simultaneous biopsy "made" the diagnosis of carcinoma in forty-three of the ninety-two patients studied and that the smear in these instances was merely a time-consuming diagnostic frill. Yet in three of these cases the first biopsy proved "negative" for carcinoma. Moreover, in thirty-two instances, biopsy was made, not simultaneously, only because the smear was positive. Furthermore, nineteen cervices which were described as "clean" or "normal" or "senile" presented no indication for biopsy prior to receipt by the clinician of the positive findings from the smear. For these reasons we are forced to conclude that a single smear is more efficacious than random biopsy in detecting early carcinoma of the cervix.

Summary and Conclusions

An effort has been made to delineate the clinical features which might assist in the selection of patients on whom cervical smears should be performed. It is apparent, as the data are reviewed, that patients who give positive smears are not clearly distinguishable, by symptoms or by physical signs, from the average "normal" controls. Pre-invasive and occasionally invasive carcinoma of the cervix may be asymptomatic or clinically undetectable, either or both. The cervical smear is positive for malignant cells in the presence of an impressively high percentage of these silent and invisable lesions. Finally, since invisibility is by no means a short-term characteristic of cervical carcinoma, the periodic "smear screening" of apparently normal women at annual, or perhaps at biannual, intervals becomes a very important aspect of preventive medicine.

ARE GRIEVANCE COMMITTEES SERVING THEIR PURPOSE?

ROBERT E. FITZGERALD, M.D.
Milwaukee, Wisconsin

IT SEEMS to me that the reasons for establishing and maintaining a grievance committee are three in number. First, in compliance with our Hippocratic oath and with our code of ethics as expressed by the American Medical Association, we are bound to make every effort to keep the practice of medicine on the highest possible level. Second, anything we may do in the way of policing our own organization will combat the adverse criticism that has flourished under the New Deal and the proposed Welfare State. Third, a concerted effort to mediate with the public, whenever real or alleged grievances are brought to our attention, constitutes the best type of public relations. It was recommended by the House of Delegates, in December of 1949, that committees be set up to hear, consider, and mediate genuine or fancied grievances, and thirty-four state medical organizations had set up such committees by September, 1950. These state committees may vary in the number of members, in the tenure of office, in the method of selection of members of the committee, but basically they are all striving for the same goal, namely to demonstrate to the public that, despite adverse publicity disseminated by the proponents of socialized medicine, the medical profession itself has a sincere desire to bring the best service to the greatest number of people. Since in many states the committees are young, they are sailing uncharted seas and each state must deal in its own way with any problems which are peculiarly its own; but all the committees are trying to demonstrate the awareness of the physician to his responsibility to his patient.

A Committee on Grievances, such as we have in Wisconsin, has, in my opinion, certain very definite responsibilities first of which is the responsibility to the public to supply it with the best possible medical care. This responsibility can be fulfilled by seeing to it that the ideals of the profession are upheld completely in the case of everyone practicing medicine: A huge task, no doubt, and one almost impossible to fulfill, but it is worth striving for. Secondly, there is the responsibility to the members of the medical profession itself. This committee examines complaints against the individual physician and, through the staff at the State Society's office, makes a thorough investigation as to the validity of these claims. When they are apparently valid, the complainant and the physician are given an opportunity to appear before the committee or to communicate with the committee and present their respective sides of the question. These are given deep consideration and, upon reaching a decision, the committee makes its recommendation to the Council of the State Medical Society of Wisconsin which body may recommend to the Board of Medical Examiners that the license of the offending physician be suspended or revoked; or, if in the opinion of the committee, the complaint is not valid or does not hold up under evidence produced by the complainant, the case is dropped and no action is taken by the Council. The Committee on Grievances in Wisconsin has no punitive power, but functions through the Council of the State Society. Another phase of the responsibility of the Committee on Grievances to the medical profession might well be considered educational, since it strives to make all members of the medical profession aware of their own responsibility to the public by observing to the letter and in the spirit all drug laws, by cooperating with the Pharmaceutical association, by working with the Bar Association on the matter of expert testimony in court, and by assisting existing government health agencies.

In discussing the functions of a grievance committee, the question of publicity arises. How much publicity should there be? In Wisconsin, the committee sent letters to judges, to health agencies, and to other organizations interested. In this last category, the Bar Association, which had made some queries concerning expert medical testimony, was especially advised of the formation of the committee and all were acquainted with its aims. To date, no complaints have been received from these groups, but the committee feels that this publicity was beneficial, since it

---

Presented before the North Central Medical Conference, Minneapolis, Minnesota, November 11, 1951.

made large groups aware of the existence of the Committee on Grievances and its willingness to work for the public good. In addition, there have been press releases announcing the formation of the committee and its objectives, so that the general public might be informed. The Committee on Grievances in Wisconsin is fully aware of the importance of absolute discretion on the part of its members so that unfavorable, or "gossip" type, publicity can be avoided. Every effort is made to keep all matters confidential, all cases are coded, and correspondence, except with the physician and complainant, is identified by code. It is essential that the existence and objectives of the committee be publicized 100 per cent among the members of the medical profession.

It has been asked, "What is the responsibility of the medical society to the physician who persists in a course of misconduct?" Our committee warns the physician that his case is being reported to the Council and that the Council will recommend a course of action to the Board of Medical Examiners. Punitive power rests with that Board and the committee can do no more than recommend through the Council. In short, the responsibility to the physician who persists in misconduct merges into the responsibility of the committee to the public.

The Committee on Grievances in Wisconsin does not function as a bill collecting agency. In my opinion, activity of that type would defeat the purposes of the committee by giving the public the wrong impression of its aims. The only economic phase with which our committee is concerned is that of the fairness of the charges made by the physician, and then only when it is drawn to our attention by a complaint, since we assume that in this day and age any right minded physician realizes the importance of fairness in the matter of bills.

I have selected three typical cases which have come before our committee, in order to give a clearer idea of the Committee on Grievances in action.

Case 1.—A child with a lacerated forehead was taken to a pediatrician during the absence of the family doctor. The pediatrician told the parents that he did not take care of this type of case and referred them to a plastic surgeon. The patient was hospitalized and three pieces of adhesive were used to bring the edges of the wound together. The pediatrician charged $15 for his advice, the plastic surgeon $50 for his call and $5 for each successive treatment. It was decided, after thorough investigation of the case, that treatment by the family physician would not have exceeded $10. This case is still pending. It is, however, typical of the overcharge claim that is made, although there are many times when a physician is accused by a patient of overcharging when the charge is just and the complaint arises from the patient's lack of knowledge of what the treatment entailed. Physicians have been urged many times to discuss possible charges with their patients before treatment so that there be no misunderstanding.

Right here it might be well to delve a little deeper into the whole question of fees and the necessity of frank discussion of the nature of his condition with the patient. Too often we hear that the doctor gives his patient too little information about the nature of his illness or, if he does make any attempt at explanation, couches this in scientific terms which leave the patient not only in the dark but with a feeling of frustration. It is highly important that the physician take the time to explain as simply as possible what the situation is. He should also point out the cost of treatment and plan with the patient how he may finance this, if it appears to be a burden. In discussion of this sort, frankness is essential. In the matter of fixing charges a doctor should consider several factors: the complexity of the job, the extent of the service necessary, and the ability of the patient to pay. A certain flexibility in adjusting his fees is often necessary when the patient's financial status makes average charges a burden. When the family doctor feels the services of a specialist are indicated he should explain this to the patient and also give him some idea of the probable charges of the specialist. In this way, many misunderstandings can be avoided and the patient will have a kindlier feeling toward the physician he knows has his best interests at heart.

Case 2.—A physician was charged by a score of people of being intoxicated while attending patients. The doctor appeared before the committee and investigation disclosed that he was suffering from multiple sclerosis and there was no indication of alcoholism. He was advised to stop the practice of medicine for the good of all concerned.

Case 3.—A general practitioner was accused of practices contrary to medical ethics and against the public interest. After appearing before the committee he was advised to consult a psychiatrist, who recommended that the physician enter an institution for treatment.

In addition, there are cases which are brought forward where there is evidence of promiscuous prescription of narcotics to addicts and others. This is often unintentional, but the committee stresses the importance of thorough investigation before prescribing narcotics and places the responsibility on the physician if this is not done.

Conclusion

In my opinion, the Committee on Grievances or the Grievance Committee, if you will, is the best instrument for implementing good public relations that organized medicine has at hand. It can do more for the public and for the physician than any other single committee within the Medical Society. Intelligent handling of medical-social and medical-economic affairs, accompanied by intelligent publicity, can do a very great deal to win and retain the confidence and esteem of the public. In its fair dealing, it bridges the gap formed by the natural reluctance of the patient to discuss his difficulties directly with his doctor and acts as a mediating board when differences arise. Members of the committee should be understanding, alert to the problems of the public and the physician, and they should be ever conscious of the paramount importance of discretion.

Since our committee has no punitive power, *per se,* it must rely upon the complete co-operation of every individual physician for its effectiveness. The fact that this committee, by its recommendations, may set in motion action which could result in suspension or revocation of a doctor's license, should act as a deterrent to that very small minority who might injure the reputation of the great numbers of conscientious members of the medical profession. In regard to the minority mentioned, we have in Wisconsin about 3,500 physicians, 3,000 of whom are in active practice. Each doctor sees at least one patient a day which would mean that at least 90,000 patients are treated in a month. The number of complaints which we have received is so small that the percentage of dissatisfied patients is infinitesimal, although it is conceded that that minute percentage can be very noisy on occasion, and, no matter how small it may be, the publicity accruing to one instance of poor or unethical medical practice makes it imperative that any committee on grievances must exert every effort to solve any question that comes before it to the satisfaction of those concerned.

Grievance Committees that function ethically and effectively will be a great factor in avoiding the political control of medicine and, in addition, they can and do protect the economic and professional status and freedom of the physician, by acting at all times in the best interests of the public. Only by proving to the people at large that our Hippocratic Oath is a living thing to us and that the desire to serve mankind, which prompted us to take up the practice of medicine, still motivates our lives can we combat the criticism which has been hurled at organized, free medicine by advocates of the Welfare State.

GRANTS FOR RESEARCH

Life insurance companies of the United States and Canada will give more than $780,000 this year for research in heart disease, as announced in March by M. Albert Linton, Chairman of the Board of the Life Insurance Medical Research Fund.

The grants being made to medical schools and to individual scientists for heart disease research this year bring to $4,700,000 the total amount of money given by the life insurance business since the Life Insurance Medical Research Fund was organized late in 1945. The Fund is supported by the annual contributions of 141 United States and Canadian companies.

Included in this year's grants are fifty grants-in-aid, totalling $641,735, being given to medical schools and research centers for the support of heart disease research, and thirty-seven fellowships amounting to $142,100 going to young doctors to enable them to obtain training and experience in research.

The resources of the Life Insurance Medical Research Fund are devoted entirely to research on diseases of the heart and blood vessels, which are responsible for more deaths than the next five causes of death combined. Since the organization of the Fund, 185 research programs and 201 research fellowships have been supported, in ninety-two institutions all over the United States and Canada.

Grants to the University of Minnesota are: for research by Dr. Nathan Lifson on transcapillary exchange of materials in perfused organs, $16,200; for research by Dr. Maurice B. Visscher on cardiovascular renal physiology, $15,335.

THE DOCTOR'S RESPONSIBILITY TO HIS PATIENT

E. M. HAMMES, M.D.
Saint Paul, Minnesota

THE doctor's responsibility to his patient is such a large one that I do not know just what your committee wanted me to discuss. Medical public relations places emphasis on the individual human relationship between doctor and patient. I thought perhaps a little homely review of some of the problems in patient-physician relationship, as I have encountered them in my few years of practice, might be enlightening. If they appear critical, I hope I will not be misunderstood.

I would like to tell you of my first personal experience of a patient-physician relationship, as it made an indelible impression on me and has been of great value to me. Having just graduated from the medical school, I decided to have a hernia operation by an excellent surgeon, a friend of my father, who referred all his surgical patients to him. On the third morning, postoperatively, I felt fine. The surgeon came to my room, looked at my chart, said a few words, and appeared unduly worried. Immediately after he left I called the nurse and asked her if I had a fever, or what not; I had quite a miserable time, emotionally for twenty-four hours, and like a real medical student reviewed all the possible complications that might develop, probably from a cerebral embolus to intestinal obstruction and everything in between. The next morning I asked the surgeon if there was anything wrong with me yesterday. When he assured me that I was progressing satisfactorily, I asked him why he looked so worried yesterday. He then told me that in the next room he had a patient, a mother with three children; he had done a thyroidectomy on her, and he was very worried and upset because he thought that she might die. This was a valuable experience to me, and I decided never to take my worries, by facial expression or otherwise, into a patient's sick room. We, as physicians, can instill into our patients the old saying, "Hope rests eternal in the soul," only by our actions, our attitude, our personality and our conversations. Fortunately, the physician of today realizes that he must treat his patient's illness not from the physical standpoint alone, but, what is fully as important and frequently more vital, from the emotional aspect as well.

Psychosomatic medicine, although it has been practiced by all of us since graduation, has become popularized during the past few years. I am sure that you will agree with me that it has stimulated us to practice better medicine, to study our patients as individuals with emotional reactions and not as a group of symptoms to be dismissed with a prescription and a statement "There is nothing wrong with you—go home and forget about it." If these patients could forget about it, they would not have to consult us. A true physician must be a good listener. The majority of our patients, as you know, suffer primarily from functional disorders, and even in the organic cases many functional and emotional symptoms present themselves. An hour spent in obtaining a careful history, with an attentive and sympathetic attitude, is frequently fully as important as our physical examination and the multitude of laboratory tests that we order. In our conference with him we can allay many of his fears and apprehensions. It may be his first operation, with all the dread of an anesthetic and the operating room. This may be time-consuming, but I can assure you his emotional reaction will be such that it will hasten his recovery. Let us not be too busy in our daily work.

The family physician has the great advantage over the specialist, in that he has extensive knowledge about his patients. Many of them he has known since birth. He is familiar with the family background, with the home environment, the school record, the mental peculiarities, if any, and the emotional set-up; in other words, he has a cross-section of his patient's life. He is the specialist in medical management and all that it implies. The family doctor has wisdom and vision, the ability to integrate and correlate findings, an understanding of human relations, a knowledge of when, where, and whom to employ for special skill, and when to do the work himself. Today, as throughout the years, he is the backbone of the medical practice, and his patient-physician relationship is more intimate than that in any other field of medicine.

Presented at the North Central Medical Conference, Minneapolis, Minnesota, November 11, 1951.

May I cite another interesting experience which I encountered: A woman, aged fifty, was referred to me because she had attempted suicide by jumping into a cistern. She suffered from an involutional melancholia, with all the fears, guilt feelings, religious worries and hopelessness characteristic of this illness. She was brought to the hospital by a nurse. As soon as I had entered the room, she dismissed her nurse, threw back the bedclothes, pulled up her nightgown, and with a terrified expression said, "Have I a venereal disease? If I have, I want to kill myself?" I covered her up and asked her to tell me her story. In brief, she had been developing her melancholia during the six months previous, and was advised by her physician to go to California, to recuperate. While she was in California, she met one of her former high school classmates. When she decided to return home, this man also went on the same train. On the way home they had sexual intercourse; she then developed a terrifying fear that she had contracted a venereal disease, and that is why she attempted suicide. I asked her why she did not discuss this with her family physician, who could have examined her and reassured her. She then said, "I could never do that and stay in my home town. His wife and I belong to the same bridge club, and he tells her everything." It is quite possible that her feelings about her home physician were delusional; they may have been, but, if true, this physician has deprived this patient, and probably others, of one of the most important patient-physician relationships—namely, the confidence in her physician. She has been deprived of the privilege to be able to go to him and unburden herself of her own worries, problems and anxieties, like she would to a father-confessor. Even the courts of our land hold sacred and recognize this, and protect us on the witness stand in this vital confidential patient-physician relationship.

It might be of interest, at this time, to refer to a brief article in the October, 1951, *Medical Economics,* entitled "Bad Manners of M.D.'s Gripe Patients Most." "It isn't exorbitant fees that raise the patient's hackels and send him running to the Medical Society Grievance Committee; the biggest trouble is just plain lack of medical etiquette." The Grievance Committee of the Iowa State Medical Society has investigated thirty-eight cases since it was organized in May, 1950. According to *Medical Economics,* the three most frequent complaints were: (1) talking to the patient too freely about another doctor's treatment or charges, (2) talking to another doctor, within earshot of the patient, about prognosis, severity of the case, finances or medical reputation, (3) failing to exercise diplomacy and tact in refusing to accept a case, make a house call, or okay an emergency prescription. Judging from the experience of this committee, we physicians as a whole either talk too much or unwisely. In this connection, it might be worth while to again remind ourselves of the fact that a great number of malpractice suits have their beginning in some slighting remark made by a physician about the care given to the patient by a former physician. This is not only detrimental to the patient-physician relationship, but expensive to the medical profession.

In lecturing to medical students, I have frequently devoted the first five or ten minutes in discussing with them problems encountered in the private practice of medicine. Unfortunately, medical students obtain very little such instruction in their curriculum. I have emphasized to them that in their private practice they will not be able to satisfy or please every patient; also that patients are not married to them and have a perfect right to another physician. If the patient or the family have lost confidence in their physician it is better for both of them to part company and it is very important to do it gracefully. Suggesting consultation may help to solve this problem or, in difficult cases, may assist in the diagnosis and treatment and undoubtedly help to share the responsibility. The consultant's attitude should be one of co-operation and assistance. His first duty is the patient. If he does not agree with the diagnosis or treatment, he should feel free to discuss this *first* with the attending physician, before talking to the family. His second duty is just as important, namely, not to say or do anything which might in any way lessen the patient's confidence in his *own* physician. He is usually the family doctor and has administered to the family for years. His third duty, if he is asked to take charge of the case either locally or in a distant town, is to advise the family physician at frequent intervals as to the patient's progress. When the family consults him, he can then discuss the patient's progress intelligently, and the patient also realizes that her own physician is

(Continued on Page 353)

INTERPRETATION OF MEDICAL CARE COSTS

J. D. McCARTHY, M.D.
Omaha, Nebraska

IF I INTERPRET correctly the assigned subject "Interpretation of Medical Care Costs," I am to discuss ways and means for impressing in the minds of laymen that the terms "medical care" and "medical care costs" are all-inclusive rather than implying, as some have, that they are the fees charged by the physician. Certainly, these terms cover the overall cost of illness, including physician's and dentist's fees, nursing care, hospital bills, fees for laboratory services, dressings, medicaments and other miscellaneous charges having to do with the care of sick people, but I believe the expression "total medical care costs" would better serve the purpose.

"My doctor bill" is the term that has always irked me when used in reference to total medical care costs. All too frequently, the flat statement "my doctor bill was so and so" is made without elaboration, and those listening are left with the impression that the stated charge representing the overall cost for medical care is only the fee charged by the physician.

How did the term "my doctor bill" come into being? It is not so many years ago that the cost of medical care had to do primarily with the physician's fee. People during that era believed that the hospital was the court of last resort, and if the physician recommended hospitalization there was no hope for recovery. Therefore only a comparative few were admitted to hospitals, preferring to stay at home for medical and nursing care. Thus it may be seen that the greatest item in total cost of medical care as of today entered only infrequently into the cost during that period and when it did, it was for only a small percentage of the total. In those days the cost for nursing care was low, fees for the few laboratory procedures were nil, roentgenology was a diagnostic tool still to come, medicaments were relatively few, low in cost, and usually were supplied by the physician. Compare this with conditions as they are today. In the past, sick people revolved around a focal point—the physician—whereas today, including the patient's personal physician, a team of consultants, nurses and technicians revolve around the patient. Recognizing the reasons for the origin and wide usage of the term, is it any wonder that it has carried on down through succeeding generations even though the aforementioned changes have taken place? The medical profession should see to it that this term is relegated into the limbo of lost words.

Other sources of misstatement of facts are found in newspaper and lay magazine articles having to do with the so-called high cost of medical care written by authors who are desirous of "giving people what they like to read" rather than the true story. Almost every day there are news items regarding someone, usually a child, who has a serious ailment, is unable to procure the services of a physician because of lack of money and must wait until friends and sympathizers contribute to a fund which will cover the "doctor's bill." Here again "doctor's bill" is a misnomer, the implication being that the physicians would not serve the individual even though he or she is in dire need of medical care. The movies also lend their aid to this misconception in much the same way. Last, but far from being the least, we have the Federal Government disseminating ideas through press, radio and pamphlets (the write-ups by the Ewing ilk and paid for with the money we ooze for taxes), which may be of value from the political standpoint but which too frequently place the physician in the role of Shylock.

Certainly something should be done to counteract false impressions fostered by such terms as "my doctor bill," if adverse publicity and public relations between physicians and their patients are to be improved. Who is to do it and how will it be accomplished? It seems natural to me that we should look to ourselves as the spearhead for such a campaign.

Statistics showing the breakdown in cost of medical care are plentiful, but I would like to quote the latest that I have seen, which were released recently by the Labor Department's

---

Presented before The North Central Medical Conference, Minneapolis, Minnesota, November 11, 1951.

Bureau of Labor Statistics. This report covers a period extending from the outbreak of the Korean War in June 1950 to the first of January 1951. During these six months the general cost of living rose 5.1 per cent; that for overall medical care, excluding drugs, 2.3 per cent; prescriptions and drugs 2.5 per cent; general practitioners' fees 1.1 per cent; surgeons' and specialists' fees 1.2 per cent; and hospital rates 4.9 per cent. It may be seen that the increase in the overall cost of medical care, except possibly that for hospitalization, is minor when compared to the overall increase for subsistence and shelter.

It would be wise for physicians to cite these figures to patients who complain about the increase in physicians' fees, and when so doing, to emphasize the many services included in the total cost of medical care. He might point out also that any increase in fees that he may have put into effect are not comparable to the increased overhead that he now carries, including rent, salaries to office personnel, cost of apparatus, instruments, medicaments, supplies and spiraling taxes.

As to the physician's fee, this should be discussed with the patient prior to rendering service. Many patients request such information and too frequently the physician evades the question. If in the mind of the patient the physician's fee might be $100 and he is presented with a bill for $200, is it any wonder that he is displeased and embittered? Physicians dealing in general practice and certain specialties—such as internal medicine, pediatrics, neuropsychiatry—find it hard to state an exact fee inasmuch as the overall services are dependent upon history and physical findings. A definite fee should be stated, however, for history taking and physical examination. It should be explained that if physical findings indicate that roentgenographic studies, blood chemistry or other procedures are necessary to make the diagnosis, the total cost will mount. Under such circumstances a cost estimate should be made before the service is rendered. Those dealing in more exact specialties, such as surgery, roentgenology, laboratory examinations, should have no difficulty in citing a specific fee to the patient which would be all-inclusive. In setting his fee the physician should take into consideration the overall cost to a patient who has to have the services of consultants, possible surgery and hospitalization, and temper his fee accordingly. Certainly the true physician will asecrtain what the individual patient may or may not be able to pay. For instance, knowing that the patient classifies as an indigent, the physician is wasting good paper and ink when he makes a charge comparable to that made for patients in even moderate circumstances. Itemized statements from physician to patient are valuable in breaking down any possibility of misunderstanding.

The great majority of patients when speaking of their physician's fee can do so, I believe, without rancor. It is only those served by the so-called iniquitous one per cent of physicians who have a just claim to having been victimized. We still have these physicians with us and I suppose we will always have a certain number, but every effort should be made to re-indoctrinate them with the teachings of Hippocrates. These few physicians can do more harm to the medical profession and its public relations program than all the good works of all the other physicians combined. Committees set up by the respective state medical societies, be they called grievance committees or committees on ethics, have a grave responsibility to ferret out all evidence pro and con when patients complain in writing that they have been overcharged. The experience of these committees indicates that the majority of complaints relative to exorbitant fees charged by physicians are based on misunderstandings, and incidentally the misunderstandings too frequently have been shown to be due to the fact that the physician did not give the patient an idea of what his charge would be before rendering the service.

The whys of the precipitous increase in cost of hospital care should be explained to the patient. Here again, demands on the hospital by physicians and patients have necessitated implementation of all services, from administration on down to laundry and utilities. The patient in the hospital today is receiving, by necessity because of advances in diagnosis and treatment, more attention than ever before. All of this calls for increased professional and nonprofessional personnel, which means more salaries, and with the trends, higher salaries. The patient should be informed, too, that although the cost of illness has increased in dollars and cents over that of some years ago, time lost from work has been considerably decreased, resulting in an actual saving for them. In other words, the hospital rate twenty-five years ago averaged $5.00 per day but the hospital stay averaged thirty days. Today the per diem charge in the hospital may average $15.00 to $17.00 but the average stay in the hospital is seven or eight days, due to the advances made in diagnosis and treatment. It may readily be seen that the total cost today approximates that of twenty-five years ago, but the days of illness and loss of time have been reduced by approximately 75 per cent.

It might be pointed out also that food purchased in 1940 at a cost of $100 now costs $251, that textiles purchased in 1940 at a cost of $100 now cost $231, that drugs and prescriptions costing $100 in 1940 now cost $182. All in all, there has been an increased cost in living, and I include under the term "living" everything necessary to life. The spiraling costs for labor have affected everything we do and everything we buy. The crude product costs no more than it ever did, but to extract that product from Mother Earth, fabricate and deliver it to the consumer has multiplied at least threefold while the dollar has been devaluated over 50 per cent. A person who is bitter because the hospital per diem charge is $15.00 does not blink an eye when he finds that the same hotel room that he had paid $5.00 for a year ago is now $8.50 per day. Add to this the cost that the hotel guest must pay for meals and it is apparent that the costs are comparable—except that the hotel guest does not have the ministrations of a nurse.

Too often we see releases in newspapers, articles in magazines, hear radio quips and government propaganda which give misleading statements regarding physicians' fees as they relate to total cost of medical care, and although we may frown, we do little or nothing to counteract the charges. There is no doubt that unfair statements, some of which could be characterized as bare-faced lies, influence the average layman in his thinking. Organized medicine, from the national to the local level, must take upon itself the screening of these releases. The American Medical Association is doing that now to a certain degree. I know of no state or local medical society which maintains a function of this character. Why should we not have, especially in our state organizations, a clipping service for articles relating to medical care costs. These articles could be turned over to a screening committee and it would be the duty of this committee to answer such articles and see to it that the answers receive wide publicity.

This is not sufficient, however. Every physician should act as a committee of one to be on guard for such disparaging items and remarks, and do everything in his power to quell further spread of these false statements. When such an item appears in a newspaper, the local physician or physicians should call upon the editor, give adequate explanation as to why the particular article is offensive or without truth, and request comparable space for clarification.

These are but some of the methods, as I see it, which if put into effect would be most helpful in breaking down charges made through habit-thought, prejudice or ignorance, and in so doing would rid the profession of unjust stigmata.

It seems to me that the term "my doctor bill" and all that it embraced in the past is to a certain degree fading out of the picture. This I believe is due to the fact that patients today are receiving separate statements from physician, consultants, laboratories, hospitals, et al, and this makes the patient realize that his physician's fee is but a part of his total cost for medical care. Another potent instrument in driving home this fact to many is voluntary prepaid hospital and sickness insurance. Here again the allowances for medical, surgical and hospital care services are publicized and in the great majority of instances broken down to show the amount allowed for medical and nursing services as well as hospital benefits. An increasing number of physicians are discussing the subject with their patients, and when they do they speak in terms of "my fee will be, your nursing fees may be about such and such and your hospital bills about so and so."

Continued publicity about differentiations between fees and the knowledge the layman is gaining through the aforementioned channels is doing much to break down a terminology which has been used not maliciously but thoughtlessly.

I would like to suggest that the Pubilc Relations Committees of our national, state and local medical societies be urged to make this entire problem one of their major projects, to the end that collectively and individually they may eradicate one of the sources which militate against improving patient-physician relations.

THE GROWTH OF PREPAID MEDICAL CARE PLANS

FRANK E. SMITH
Chicago, Illinois

BEFORE delving into detailed data regarding the current status and recent developments of Blue Shield Plans, it might be well to spend a moment describing the background and organizational relationship between Blue Shield Plans and the medical profession.

At the Interim Session of the House of Delegates of the American Medical Association in December, 1945, a ten-point program was adopted, one portion of which gave American Medical Association endorsement to the principle of voluntary health insurance. Following the adoption of that policy statement, the AMA Board of Trustees and the Council on Medical Service took steps to establish a national organization of medically sponsored prepayment plans in operation at that time.

Out of the conferences between the Board of Trustees, the Council on Medical Service, and representatives of the medically sponsored prepayment plans, there was chartered in Illinois in March, 1946, a nonprofit association known as Associated Medical Care Plans.

The principal reason for Associated Medical Care Plans being established as a separate corporation was the then recent experience of the American Medical Association in a Supreme Court hearing, and several tax litigations, following which it was felt that such an organization as Associated Medical Care Plans and its intended functions could be best carried out through an independent corporation, rather than for such activities to be carried on by the American Medical Association iteslf.

Nine prepayment plans became the charter members of Associated Medical Care Plans in March, 1946. In December of the same year, nine additional Plans had applied and had been admitted as members of the association, and national headquarters and staff were established in the AMA headquarters building in Chicago.

As indication of the growth in member Plans, it can now be reported that the original nine charter members have been expanded to seventy-eight member plans, operating in forty-two states, the District of Columbia, Hawaii, Puerto Rico, and eight Canadian provinces.

Since the association was established in 1946, a brand label, known by the name Blue Shield and visualized by the Blue Shield symbol, was adopted in 1948 and is now in general use among the seventy-eight member plans of the association. At the present time the entire movement is known rather widely by the American public as the Blue Shield Plans. Appropriately, the name of the association was changed, in the early part of 1950, from Associated Medical Care Plans to Blue Shield Medical Care Plans.

Membership standards have been adopted by Blue Shield Medical Care Plans and any medically sponsored plan wishing to become a member of the association must meet those membership standards before acceptance by the association can be assured. In addition to standards calling for efficiency of operation, conformity with general standards of good insurance practice, and integrity of operation, these standards call for free choice of physician, sponsorship or approval by the medical society in the area served by the Plan and operation on a nonprofit basis.

With very few exceptions, the Blue Shield Plans include in their membership practically all of the medically sponsored programs for the prepayment of medical care.

Blue Shield Medical Care Plans is governed by a commission, known as the Blue Shield Commission, elected by the Plans themselves. The Plans are divided into eleven districts, with each district electing two members to the Commission, one representing the executive directors and the other representing the governing boards of the Plans in the district. In addition to the twenty-two members of the Commission thus elected, there are at present three Commission members elected at large, those three being Dr. Paul R. Hawley, Director of the American College of Surgeons, Dr. Charles Gordon Heyd, President of United Medical Service in New York and former President of the American Medical Association,

---

Presented at the North Central Medical Conference, Minneapolis, Minnesota, November 11, 1951.

and Jay C. Ketchum, Executive Vice President of Michigan Medical Service.

At the next annual meeting of Blue Shield Plans, to be held in San Francisco in April of 1952, five additional members at large will be elected, having already been nominated by the Blue Shield Commission according to the provisions of the By-Laws, and including Doctors A. J. Offerman, Omaha; R. L. Novy, Detroit; L. Howard Schriver, Cincinnati; Carlton E. Wertz, Buffalo; and Paul R. Hawley, Chicago.

The national association is strictly a voluntary matter as far as affiliation is concerned. It has no supervisory or disciplinary authority, insofar as its member Plans are concerned, except for the right to determine whether or not a member Plan has continued to comply with the membership standards which constituted the basis for the Plan's original acceptance as a member. The principal functions of the national organization are comparable to those of a trade association, in which the national organization seeks to render services which are beneficial to and of mutual interest to the member Plans. In this sense, it might be said that the national organization serves as a co-ordinating agency. It might also be described as an organization which serves as a "clearing house" of information and the sponsor of conferences and activities calculated to serve the needs of the member Plans.

It is always of interest to those who are only slightly acquainted with Blue Shield to know something about the accomplishments of these Plans in enrolling members.

At the end of the year 1950, the total enrollment among the American people for hospital coverage written by nonprofit agencies as well as commercial insurance carriers, reached 76,961,000, which was a gain of 17 per cent over the preceding year. Of these nearly 77,000,000 people, approximately 54,500,000 had also purchased protection for surgical benefits, amounting to a gain of 32 per cent over the preceding year, and 21,500,000 had purchased protection for medical care, which was a gain of 28 per cent over the preceding year.

Figured into the totals indicated above was an enrollment of 38,822,000 in Blue Cross for hospitalization coverage, or approximately 50 per cent of the total number of persons protected for hospitalization. Medically sponsored nonprofit Plans claimed a membership of 19,690,000, or approximately 37 per cent of the total number of persons protected for surgical and medical benefits.

It gives me a great deal of pleasure to announce the fact that Blue Shield Plans alone, exclusive of other medically sponsored organizations, are able to say that, as of September 30, 1951, there were 21,000,000 persons enrolled by Blue Shield. On next Tuesday evening, November 13, we will be celebrating that fact at a dinner party in the new office building of the Minnesota Blue Cross and Blue Shield Plans, when a certificate will be awarded by the Blue Shield Commission to Miss Rosemarie Hart, a stewardess employed by Northwest Airlines, who has been selected as the 21 millionth Blue Shield member in the United States and Canada. At the same time, we will have the additional pleasure of presenting another certificate to an employe of Northern Ordnance Company as the 500,000th member of the Minnesota Blue Shield Plan.

I might add, parenthetically, that the Minnesota Blue Shield Plan has made one of the most enviable records of any Plan in the United States, having begun enrollment only four years ago and having accomplished in the space of four brief years the enrollment of more than one-half million members in Minnesota.

It might assist in the visualization of this rather phenomenal enrollment picture to reduce this accomplishment to working day figures and tell you that Blue Shield Plans throughout the United States are adding more than 28,000 new members every working day.

Among some of the more significant groups to be added to Blue Shield during recent months have been the employes of U. S. Steel Corporation, Bethlehem Steel Corporation, Republic Steel Corporation, and the vast DuPont industrial empire. During the third quarter of 1951, Blue Shield, by virtue of the enrollment of U. S. Steel and Bethleman alone, added more than 1,100,000 members.

Some of you will be interested in a brief progress report on the development of National Blue Shield Service, Inc., as a national enrollment agency for Blue Shield Plans. I believe you will be interested because of the controversy which surrounded the original proposals of nearly three years ago, when it was first suggested that such an agency might be formed for the purpose of assisting Blue Shield Plans in the enrollment of large national accounts.

Even though the American Medical Association expressed opposition to the original proposal, which was a suggested stock insurance company to be formed by Blue Cross and Blue Shield jointly, and later expressed a feeling that Blue Shield should be allowed to use its own good judgment when it proposed to establish its own national enrollment agency, quite apart from that being formed by Blue Cross, the Blue Shield Plans proceeded with the latter proposal, raised $383,000 among themselves, and received a charter in the State of Ohio for National Blue Shield Service, Inc., in December of 1950. The company was granted a license to do business in Ohio in May of 1951, and is currently applying for licenses to do business in additional states. The agency is not yet prepared to serve its original purpose, nor to do business, but it is expected that before the end of this year it will be in a position to fulfill its intended function.

Financially speaking, the Blue Shield Plans have shown equally phenomenal progress, as evidenced by their rapid increase in enrollment. During 1950, the Blue Shield Plans had a national income in excess of $150,000,000 of which approximately $116,000,000 was paid to the physicians for more than 7,000,000 professional services rendered. The amount paid to physicians was approximately 79 per cent of the total income, with approximately 13 per cent being used for operating expenses, and the remainder being held for reserves.

On the basis of reports for the first six months of 1951, the Blue Shield Plans will have a total income this year of approximately $240,000,000, with somewhere in the neighborhood of $200,000,000 being paid to physicians for professional services.

Financial reports for the first six months of 1950 indicate that utilization has increased from 79 per cent to approximately 82 per cent, and operating expenses have been reduced from 15 per cent to approximately 12 per cent.

One of the unique characteristics of Blue Shield Plans, as contrasted to the offerings of the commercial insurance industry, is the principle of service benefits.

Service benefits are best described as a provision in the subscriber certificate which guarantees to the subscriber that, if his or his family income is within certain prescribed limitations, the attending physician will render professional services for the fee set forth in the Plan's fee schedule without any additional charge. This puts Blue Shield Plans in the position of offering to millions of American people the privilege of exchanging premium dollars for medical or surgical services without red tape or additional bills from the attending physician.

This principle has been subscribed to by the majority of physicians in the United States to the extent that fifty-eight of the seventy-eight Blue Shield Plans are able to offer these benefits to their subscribers within certain income limitations.

There is no longer any doubt about the level of public interest or demand for such benefits, once the principle has been established and becomes familiar to the subscriber.

The inclusion of the service benefit principle in the operation of a Blue Shield Plan has raised and will continue to raise several important problems as far as the physician is concerned. The first question to be met is the degree of willingness on the part of the individual physician to accept the principle and sign an agreement indicating his willingness to participate. Beyond that point, however, are the broader questions of medical control over the Plan to which a physician is asked to commit himself, and the safeguarding of professional and ethical standards in the administration of the Plan which proposes to offer professional services to the public on a service basis.

The medical profession, individually and collectively, has not yet fully made up its mind regarding the service benefit principle, but there has been established during recent years a very definite trend toward its increasing acceptance.

To the degree that the service benefit principle is accepted universally by the profession and offered to the American public through the instrument of Blue Shield Plans, will Blue Shield fulfill its unique function, serving both the public interest and that of the medical profession in its effort to solve the problem of medical costs and forestall the threat of federal control over matters of health.

It might be of interest to cite the fact that there are approximately 1200 board members serving on the boards of these seventy-eight Blue Shield Plans, of which more than 750 are doctors of medicine. Although the average ratio is two physicians to one non-physician, there are still some Blue Shield Plans in which the medical profession is not sufficiently represented to assure the doctors of the kind of control to which they believe they are entitled. In approximately the same degree in which the doctors do not have a feeling of complete confidence and control will one find that service benefits are not acceptable or not likely to be for some time to come.

As a summary of the present status of service benefits among Blue Shield Plans, let me repeat the fifty-eight of the seventy-eight Blue Shield Plans are offering service benefits to the American people on some basis. A few of these Plans have no income limits for the determination of eligibility, but offer the services of the profession to any subscriber regardless of income. The majority of these fifty-eight Plans, however, offer service benefits to subscribers whose annual incomes fall within established limits, which range from $1,800 for the individual subscriber to as high as $6,000 for the family.

More than 115,000 physicians have signed participating agreements with Blue Shield Plans. The average rate of participation on the part of physicians, with Plans offering service benefits, is 87 per cent of physicians in active practice.

There is a trend among Blue Shield Plans toward the increase of income ceilings within which subscribers will be eligible for service benefits. These increased income ceilings represent, not so much a change of attitude or policy on the part of the medical profession, but an adaptation by the Plans to the economic facts of life, particularly those which have been caused by the period of inflation through which we have been living.

A Plan which several years ago offered service benefits to subscribers whose incomes were less than $3,000 per year for the family was making an offer that encompassed perhaps 65 or 70 per cent of the population. Today, those same income limits would exclude all but a small portion of the population, and the increases in income ceilings have been made in order to restore eligibility to the same portion of the population as was originally eligible some years ago.

One of the important trends among Blue Shield Plans at the current time is the trend toward new types of coverage, usually of a more comprehensive nature.

It must be admitted that competition between Blue Shield and commercial insurance carriers has been forcing a great deal of this expansion in terms of benefits and additional coverage. To a large degree, however, public acceptance of the principle of health insurance and public demand for more comprehensive coverage have accounted for a greater portion of the expansion which has taken place in recent years.

The chief limiting factors on the expansion which has taken place, or which might be expected to occur in the years to come, are the fundamental principles of insurance by which all Blue Shield Plans must be guided, and the period of time required for experimentation and acquiring of experience data on new types of coverage. The expansion of Blue Shield into more comprehensive types of protection is based upon mathematical calculations. Such calculations cannot be made without adherence to certain established principles of insurance and controlled experience in the development of data upon which such calculations can be projected.

The two most significant types of expanded benefits which have been introduced recently are those which have ventured into the field of catastrophic illnesses and those which are being projected into the realm of deductible certificates, in which the insured member pays an initial amount for services rendered, after which the Plan's benefits become effective. The latter is comparable to the familiar type of automobile insurance that all of us have purchased during recent years.

Every doctor is familiar with the problem of hospital-physician relationships, such as have been highlighted by the Hess Report recently adopted by the American Medical Association. Blue Shield Plans, acting through the Blue Shield Commission, have expressed themselves as feeling that Blue Shield should not become a party to such controversies and, further, that Blue Shield should not permit itself to be used by either one or the other party to such a controversy in forcing its objectives upon either the hospitals, doctors or the public.

It has been expressed frequently, in Blue Shield circles, that the controversy between hospitals and doctors will have to be settled by the two parties directly concerned, and that, once an agreement has been reached, the policies and practices of

(Continued on Page 349)

HOSPITAL ADMINISTRATION AND THE MEDICAL STAFF

K. S. KLICKA, M.D.
Minneapolis, Minnesota

IN discussing this somewhat delicate subject of the relationship of the hospital administrator and the medical staff, I will make every attempt to present it in as unbiased and impartial a fashion as possible—difficult though this may be. I will at least attempt to reflect the same honesty as was shown by a fine old gentleman of the Confederacy who once wrote a book which he entitled "An Unbiased History of the Civil War from the Southern Point of View."

In addressing you here, I will use the pronoun he in referring to the hospital administrator. In so doing, I conform with a basic rule of grammar with which you are familiar and for no other reason. Women play an important role in the field of hospital administration. Many of our hospitals, including those operated by Catholic orders, are well administered by women, so it is by no means a man's field. And perhaps this is well, for women bring to this specialty a graciousness and tolerance that it needs. These are qualities that too frequently are lacking in man. Here at St. Mary's you are blessed with an administrator who possesses these graces, and you are indeed fortunate. Your hospital as a consequence reflects a personality that extends far beyond your city. Such reputations are not easily come by; they are created by the daily devotion to an ideal and a creed that spells service to the community.

James F. Bender, director of the National Institute for Human Relations, describes the ideal hospital administrator as a person who must possess the friendliness of a General Eisenhower, the brains of a Herbert Hoover, the power of expression of a Winston Churchill, the resilience of a President Truman, the energy of an Eleanor Roosevelt, the spirituality of an Albert Schweitzer, and the eagerness to heal of a Sir William Osler. Is it any wonder that a good hospital administrator is hard to find?

You as a medical staff and I as a hospital administrator have many reasons to regard each other carefully as we do our daily work. To be successful in our task we must carry on with the thought that we play on the same team. Our problems then become our mutual concern, and we should try to solve them together. Sorry indeed is the hospital where the administrator, in evaluating his many problems, places his medical staff at the head of the list. If he does so, the blame may be his as well as the staff's, but most likely it is the fault of both. Ofttimes it is diffcult for both parties to clearly see the same goal, or in seeing it to achieve it by the same means.

It is my impression that a hospital serves its purpose when it provides the best and most complete medical care for its community at the lowest possible cost. You and I have our individual responsibilities in providing this type of service. Just what are they?

First as to the administrator. He should try to instill in his personnel a feeling of humaneness and kindness. He can receive no higher compliment than to be told his hospital is a friendly one.

> So Many Gods, So Many Creeds;
> So many ways that wind and wind;
> Yet just the art of being kind,
> Is all the sad world needs.

Edna Wheeler Wilcox, who composed these few lines many years ago, has given us our challenge.

But being kind and considerate isn't enough. The hospital administrator today combines kindness with firmness to insure that proper procedures are carried out at the patient's bedside; to assure you that the nurses, practical nurses, attendants, aides and maids carry out their duties as best they can; to assure your patients of receiving the care prescribed by you in the order book. Furthermore, your patients are entitled to top quality food, prepared well and attractively presented.

The diagnostic services of the laboratory and x-ray departments must be geared to the needs of the staff. The pathologist must be alert to the newest in diagnostic aides and then make them available to the staff. The roentgenologist, in addition to providing top quality films and accur-

---

Dr. Klicka is director of St. Barnabas Hospital, Minneapolis.

Read at the annual meeting of the medical staff of St. Mary's Hospital, Duluth, Minnesota, February 7, 1952.

ate interpretations, must also offer the latest in therapy. The pathologist and roentgenologist more often than not determine the quality of medical care in a hospital. It is frequently their responsibility to set the standard of practice. It is within their scope to lead.

Hospital service is expensive, but it has always been so. Perhaps it seems more so now than ten to fifteen years ago, but actually this is almost entirely relative. Drugs make up a sizable portion of the total hospital cost today, and they are more expensive than the simple pharmaceuticals of earlier years, but largely because of them our patients recover more quickly and consequently spend fewer days in the hospital. The disease that may have kept a patient in the hospital three weeks ten years ago can now be cured in a week. Our personnel are better paid today than was true before World War II, and this change was long overdue. An administrator friend of mine has put it well by saying that hospitals are not only having to keep up with the present inflationary cost of living trends but also have had to escape from the Old Lady Bountiful attitude of providing a starvation wage and promising a future golden harp and a special cloud in heaven. Our employes are more sophisticated now; they prefer to eat today and worry about the harp later. The hospital administrator cannot disregard the needs of his employes any more than his trustees can overlook the salary requirements of employes in their own private enterprises. Unfortunately the hospital administrator cannot perform miracles in creating a fund from which money for salaries can be drawn. Higher charges for hospital services and efficient operation are the only answers.

In approaching the purchase of a new car, a man naturally compares its price to that he purchased five years ago. This applies to those few among you who can wait that long to change models. The price increase in this short span is enough to shake one somewhat. The car salesman never apologizes for this increase, however, but merely points out that the new car is worth more. The same can be said for your patient's hospital bill. Of course it is high but it is worth it. If ever a commodity was worth its cost, it is present-day hospital care. Although the cost per day of hospital care has risen considerably in the past decade, the cost per illness has not. Recent studies which take into consideration the shortened hospital stay and relative purchasing power of the dollar show quite convincingly that in comparing the three-year span of 1948, 1949 and 1950 with that of 1938, 1939 and 1940 the increased cost per admission is only 11 per cent. It should be an easy matter for any of us to demonstrate that there has been much more than an 11 per cent increase in the scope and value of the service that a hospital is offering its community today. Furthermore, this small increase is more than offset for the wage earner who returns to work more quickly than was true ten years ago, thereby significantly reducing his loss of earnings because of his illness.

The rising cost of hospital care was recognized as a threat to our voluntary system of hospitals as long ago as 1929. This recognition led to the idea that hospital care could perhaps be prepaid, thereby becoming less of a burden to anyone who was hospitalized. Blue Cross was the name applied to this idea, and as we look back over its twenty-two-year history with some pride we see the justification of the effort that went into its development. By 1940 the number of individuals throughout the country covered by Blue Cross slightly exceeded 6,000,000. The next ten years saw an amazing growth and at the end of 1950 the number of subscribers was 39,000,000. Commercial insurance companies recognized an opportunity for service in this field and became very active. In 1940 approximately 4,000,000 people were covered either by group insurance or an individual policy. In the ten years ending with 1950 this number increased to 40,000,000. By the end of 1950, allowing for duplication of coverage by Blue Cross and commercial insurance companies, the total number of persons covered against hospital expense exceeded 77,000,000. More than half the population of the United States are therefore protected against the unexpected expense of a hospital bill. By states, the proportion of population covered varies somewhat over the country. By the end of 1951, 1,000,000 persons were covered by Blue Cross in Minnesota or approximately 33 per cent of the population. Unfortunately exact commercial insurance figures are not available. Such insurance is quite popular, however, especially in the larger metropolitan areas of the state. Again allowing for duplication, it is estimated that 60 per cent of the population of Minnesota is covered by these two forms of hospital expense insurance.

While the prepaid hospital care plans were developing, the surgical-medical expense plans were also coming along. In 1940 only about 2,500,000 people were covered with some form of surgical expense policy. In the next 10 years the number covered by commercial group insurance companies showed a gain of nearly 20,000,000; the Blue Shield grew at a similar pace and also covered 20,000,000 individuals by the end of 1950. The number of persons covered under individual policies increased by 13,000,000. The total number of individuals covered with some form of surgical expense insurance in 1950 was 54,500,000.

Medical expense coverage is also growing. In 1950 the number of individuals covered exceeded 21,500,000, of which 11,500,000 were covered by Blue Shield.

And to those who may believe that the peak in voluntary enrollment in prepayment and insurance plans may now have been reached, the 1951 figures will be interesting. Although exact tabulations have as yet not been completed, the best estimates show that well over eighty million Americans (perhaps as many as eighty-five million) now carry hospitalization insurance. Some sixty million are also insured against surgical costs; some twenty-five million against medical costs.

Are we going to have socialized medicine in this country? A fair evaluation of the figures I have given you leads me to answer a firm *no* to this question. The tremendous rise in voluntary health coverage reflects the growing desire of the American people for protection against the economic hazards of sickness and accident through plans of their own choosing. We in the hospital-medical fields are definitely in high gear and are approaching the crest of the hill labeled "total voluntary health coverage of the population." The steepest part of the grade is definitely behind us. Henry J. Kaiser phrased my *present* attitude on this for me a few weeks ago when he said "Since you can't be clairvoyant, you've got to be optimistic."

One important fact must never be overlooked, however. Although we have come a long way in a short time, our progress must be protected. It is you, the medical staff, who have this responsibility. When a doctor prescribes hospitalization, he refers the patient to a hospital and Blue Cross pays the bill. It does not question through lengthy questionnaires the recommendation of the physician. It thus places its very existence in the hands of the medical profession. In turn, it must depend upon doctors for protection against possible abuse. In contemplating the ordering of a laboratory procedure or an x-ray, either of which might have questionable value in assisting in the diagnosis of your patient's illness, keep in mind that it is not free, and let your decision be made accordingly. Similarly when considering the time of discharge, let your patient's condition be your sole guide. Avoid the practice of letting your patient stay an extra day because she is enjoying the rest and because it won't cost her anything. Keep in mind that these two examples are the basis of that which we call abuse. Neither of these services are free. Certainly they do not add to the cost of this period of hospitalization, but the total cost of your patient's hospital stay makes up a part of the over-all average cost which is used as the basis for next year's premiums.

Many people, some doctors included, are under the erroneous impression that health insurance actually lowers the cost of hospital care. It does not; it cannot lower it one penny. It serves merely to spread such cost. Therefore, the greater the cost that needs to be spread, whether this be due to abuse of the contract provisions or to some other factor, the higher the rates for such protection will climb, until finally it will be beyond the ability of all to carry heath insurance except the well-to-do; and this, as we all know, is becoming a smaller and smaller group.

While we defend the progress we have made in prepaid health protection plans, we must also be vigilant against subtle methods of attack. President Truman, by the creation of the commission on the health needs of the nation, has brought about a diversionary movement for the purpose of momentarily clouding the issue. It is interesting that he should create such a commission in an election year with a specific limitation in its action for one year—this, in spite of the monumental proportions of the outline of objectives. Such a survey could not possibly be accomplished with either accuracy or adequacy within less than three to five years. Dr. Gundersen of La Crosse, Wisconsin, in refusing to serve on the commission, states, "I believe I am correct in assuming that the commission is designed both in its majority membership and in its objective as an instrument of practical politics to relieve President Truman from an embarrassing position as an unsuccessful advocate of compulsory health insurance." Significantly, the year designated for the commission's study is the election year of 1952 when the President and Congressional candidates who have supported his socialized medicine proposals may find it politically expedient to avert a showdown before the people by stating that the whole subject is under study by a Presidential commission, and is therefore not an issue in the election. I can't say as I blame them for running and hiding on this issue but let us not be fooled by this device. Our enemy has chosen a strategic retreat at the moment; if given another opportunity in the future he will attack again.

Let there be no misunderstanding of the fact—the only reasons we criticize the President's commission are those that have been stated. The health needs of this country should be studied, and as a matter of fact they are. The Brookings Institution's two-year study of the availability of medical service in the United States, covering many of the subjects mentioned in the President's directive to the commission, will be completed this year. A new study on the financing of hospital care is being undertaken by the Commission on Financing of Hospital Care. This project is being underwritten by a group of five philanthropic foundations including the Kellogg Foundation and Rockefeller Foundation. Furthermore the studies of the Council on Industrial Health, Council on Medical Service, and the Committee on Federal Medical Service, all of the American Medical Association, continue. No one can say that our program is static, a status quo plan; nothing could be further from the truth. Let us be on guard, however, should it ever be thus described. The public is entitled to know the full truth, and I think they will get it. The public relations program of the American Medical Association is working hard to keep our citizens informed, but they cannot do the job alone. This is your fight and you can do much by keeping abreast of the activities of your Association, and participating actively in your country society. The "let George do it" era is gone. The success of the American Medical Association depends upon two things: the interest and vigor of its membership, and its leadership; and the first pretty well controls the second. It functions as a democracy and its life therefore is dependent upon its constituents. When you criticize the office on 535 North Dearborn Street, first ask yourself whether you in any way participated in their policies, either actively or passively. Have you done anything to help?

A few paragraphs back I stated that we were rapidly approaching the crest of the hill entitled "total voluntary health coverage." Well, there are a few dangerous curves ahead, but they are well posted. If we use the proper caution, as we keep our foot on the gas, we should easily reach our goal.

In rambling as I have from the direct subject of the hospital administrator, I hope I have not become so vague as to lead you to miss the point. It is this. That the hospital administrator of today is interested in more than just the running of his immediate hospital. He has to be. His total interest in the hospital field has led to better hospital service and to better hospital economics. Blue Cross is one of his inventions. The plan was conceived, organized and developed by the American Hospital Association, and the membership of this organization is made up of hospital administrators. Remember also that Blue Shield grew out of Blue Cross, and today the two serve as our weapons, as our spear and breast-plate in our conflict with inflation and its ravages to the economy of our civilization. Further, it is helping us to preserve and continue on a voluntary basis, free from governmental control, a system that is setting the standard for the world in hospital and medical care.

And now for a few words about the medical staff. What are your responsibilities on the team? The hospital owes much to all of you, but what about your obligations to the hospital? In searching for the answer to some of these questions, it might be well to review briefly some of the accomplishments in medicine in recent years.

Back in 1910 the death of fifty to sixty mothers was the price paid for every 10,000 babies born alive in Minnesota. By mid-1951 we were losing only four mothers for every 10,000 live births. Infant deaths have been greatly reduced. In 1910 approximately ninety-seven babies of every 1,000 born alive in Minnesota died before reaching their first birthday. During 1951 only twenty-four babies in 1,000 died in their first year.

As babies grow and become children, their parents no longer need fear the scourge of the deadly communicable diseases. Immunization, improved sanitation and better medical care are responsible for this change.

The sulfonamides, penicillin and the newer antibiotics, aureomycin, terramycin and chloromycetin, are such wonderful pharmaceutical tools that one really wonders how we were able to practice medicine at all without them ten years ago. Literally hosts of diseases for which we had no specific a few years ago now respond quickly to treatment. Advances in surgery have also been dramatic. Successful surgery is being performed on the gastrointestinal tract, the heart and lungs and the brain that was considered impossible ten years ago. The advances in the use of parenteral fluids including blood have been spectacular. Blood banks are an invention not alone of this age but of this decade! This fall at St. Barnabas Hospital one of our surgeons in the course of his research with parenteral feedings maintained a patient at a normal fluid balance and a constant weight for forty-three days on intravenous feeding alone. Every branch of medicine has had its advances and you have been responsible for them. The medical profession has much to be proud of. Its record is indeed a brilliant one. We are living in an age of medical miracles, and I for one am thrilled to have had the opportunity to have lived during it.

The hospital administrator and the physicians of the staff have been going forward together. Medical and hospital care has been constantly improved, and means have been found for the citizens of our communities to pay for it.

Let us return more specifically to the subject concerning the medical staff and its responsibilities to the hospital. Where and how do you, as individuals, fit into the picture I have painted? How do you stand in your own self-analysis as regards the quality of medical care you practice? How many surgeons here nodded their heads knowingly when they read Dr. Ravdin's lead article in the *Journal of the American Medical Association,* a few weeks ago, wherein he discussed the surgeon's responsibility to the community. It seems parts of our country are still somewhat plagued by the problem of splitting fees and the performance of "ghost surgery." How many hospital staffs in the country today are willing to submit to a regular professional audit of work performed? This has been the most successfully ignored recommendation of the American College of Surgeons in the past thirty years. Why? Why is it that so many doctors resist an audit of their professional activities? This question has bewildered many for many years. How many physicians who include obstetrics in their practice do so in a way that would make their medical school professors proud to have been their teachers? Are you patient, do you use caution in using analgesia; is induction used sparingly and only after the mother has been given a fair chance of going into and proceeding through labor normally; is cesarean section only performed when a clear-cut defendable indication presents itself; are mid and high forceps used without adequate knowledge of their dangers? A great challenge continues in obstetrics, for in spite of the tremendous reduction in infant and neonatal deaths in the past twenty-five years, considerable improvement is still thought possible. Immaturity, the leading cause of infant deaths, ranks as eighth in the list of the ten leading causes of *all* deaths. In 1950 in Minnesota, 520 infants died from immaturity; 252 infants died in 1950 from birth injuries. Almost as many deaths occur in infancy as there are in all of the next thirty-nine years of life. Maternal mortality in Minnesota was reduced to .58 per 1,000 live births in 1950 and still lower to .4 per 1,000 live births for the first half of 1951. Minnesota can well be proud of this record. Yet of the forty-four deaths that occurred in 1950, the maternal welfare committee judged that thirty-three were preventable.

To what extent do you assist and participate in the intern-resident training program in the hospital? Does your house staff say that your training program is giving them everything they had hoped it would. Do you teach in return for your interns' services to your patients? Do you support the academic program of your hospital by regularly attending the clinical-pathological conferences, section meetings and general staff conferences.

The hospital administrator is interested in all that you do, for what you do pretty well determines the reputation of your hospital in the community. The hospital administrator, you see, has responsibilities beyond those of just running a good hotel. It is his job to work with those on the staff who will co-operate with him in maintaining a quality of care in the hospital. As I have tried to point out, quality is your business and something every physician has or should have the ability to give. In the hospital where the staff renders the highest quality of medical care and the administrator keeps things humming efficiently with warmth and understanding, we truly have the millenium.

As you know our parent organizations, The American Medical Association and the American Hospital Association, have not been on the best of terms in all matters in recent years. As 1951 progressed, however, the air cleared considerably, and a definite change in relations became apparent.

The attitude expressed at the convention in Los Angeles that "there can be no exploitation of the doctor or of the hospital if everyone concerned will work together to supply the greatest possible good quality medical and hospital services to the public" indicates a new appraisal of hospital-physician relationships. Three major policies were modified.

1. The threat to drop offending hospitals from the AMA approved list, where or when a physician providing a professional service has been found to be unethical, has been lifted.
2. The ethical dilemma of many salaried physicians has been eased to some extent. Although still warned against working for hospitals, medical schools, and the like, under conditions which permit the sale of their services by their employer for a fee, the real ethical test, it now appears clear, is whether any "exploitation" exists.
3. The matter of submitting doctor's bills as separate from hospital bills has been clarified so that the recommendation now reads "the cost of medical service rendered in hospitals should be separated from non-medical costs, as can be done by existing and accepted methods of cost accounting, and should appear thus separated on the statement submitted to the patient." In other words, joint bills rather than separate bills have AMA approval.

Like the story of the man who called his doctor and said, "Please come over quickly. My wife is very ill. I'm sure she has appendicitis and needs an operation." The doctor said, "Why, I took her appendix out three years ago. Who ever heard of a second appendix?" The fellow said, "That's right, doc; but did you ever hear of a second wife?"

Things are changing with us also. A realization that we need each other, and that this is no time to have differences, is rapidly spreading among administrators and physicians alike. Hospitals are your workshops; they are mere shells without you. A hospital without physicians is like a school without a faculty. You, in turn, are like professors without colleges, without them. We are completely dependent upon each other, and it seems in most instances, pleasantly so, as a wife is to a husband. It is a happy marriage. It is a union we should nurture and enjoy. We have similar problems and purposes. We both exist to care for the sick. We have become so close in our relationship that anything that affects one quickly affects the other. Should government gain control over hospitals you would not long continue as completely private practitioners. If the reverse should occur, the change would take place even more quickly. Socialized medicine today would mean socialization of the voluntary hospital system tomorrow.

In closing, let me again repeat the word team, and remind you that if we are going to win the game of health we are playing, we had best get our signals straight and play as though we attended practice regularly. Our opponents are sharp, well disciplined and powerful. We, however, have the spiritual advantage. We also know that in spite of errors and hesitancy along the way we have done a pretty good job. Teammates keep up each other's fight by example, encouragement and constructive criticism, not by back-biting. This is our cue. If we are going to win the fight to continue our voluntary system of hospital and medical care, we must pull together. Let's take this next kickoff and really carry the ball.

Every general hospital can speed the ultimate eradication of tuberculosis in this country by adopting its own tuberculosis control program. This program should emphasize at least three features: routine admission chest x-ray films for all patients and periodic chest x-ray films for personnel; isolation precautions for patients with sputum containing acid-fast bacilli; and provisions for prompt therapy of all patients found to have active pulmonary tuberculosis. No matter how large or how small the general hospital, it can find a form of routine x-ray examination best suited to it. Indeed, if a general hospital is to provide adequate medical and surgical service to its patients, it must have some type of admission chest x-ray inspection.—Sydney Jacobs, M.D., *Diseases of the Chest,* November, 1951.

MEDICAL TECHNOLOGY

SISTER M. ALCUIN, O.S.B.
Duluth, Minnesota

PRIOR to the time of Osler's publication in 1892 of *"Principles and Practices of Medicine,"* the average physician was expected to perform practically all of the prevailing laboratory procedures: urinalysis, few simple blood counts, gastric analysis, sputum examinations and some simple bacteriology. About this time the interns appeared on the scene and in the larger hospitals they were responsible for the laboratory tests. Prior to World War I "trained workers" were available to a limited extent. At the close of World War I, the pathologist, becoming established, often did the laboratory work: routine blood counting and urinalysis, sectioning surgical specimens and staining them, not to speak of washing and cleaning his own glassware. By this time, society was accustomed to seeing high school girls—some graduates and some not—working with doctors in their offices and in clinical laboratories under medical supervision learning medical technology by preceptorship generally.

According to Virchow, the seventeenth century was the century of the anatomical laboratory, the eighteenth the clinic, the first half of the nineteenth the physiologic institute (first seen in Breslau in 1825), and the second half the pathologic institute (the first being that of Virchow's in Berlin 1856).

About the beginning of the twentieth century, medicine had developed to the point where a new type of laboratory was indicated—the clinical pathological laboratory. In America it was accepted as an entity and defined in 1924 by a joint committee of chemists, bacteriologists, pathologists, and physicians thus: "A clinical (pathological) laboratory is an institution organized for the practical application of one or more of the fundamental sciences by the use of specialized apparatus, equipment and methods for the purpose of ascertaining the presence, progress and source of disease." Its prototype first appeared on the continent in Leipsic in 1892, in Munich in 1894, and in America at the University of Pennsylvania in 1895.

The beginning in America of the clinical pathological laboratory was a humble one. To illustrate: In 1896 Johns Hopkins set aside a 12 x 12 foot room for "extensive tests." Its equipment consisted of a chair, a modest stool, some simple tables, wall shelves, two monocular microscopes, some test tubes and racks, and bottles. The doctor-director thought: "While running water and gas are helpful adjuncts, the ordinary water-bottle and spirit-lamp are all that is necessary." There were major and minor objections against constructing clinical laboratories in hospitals—laboratories such as are now seen not only in hospitals but in every clinic and to some extent in progressive practitioners' offices. In 1901, these were the major objections reported: they were a scientific luxury, space-consuming, expensive, and an imposition on an already busy hospital intern; the minor: the fear that patients might drink some of the poisonous laboratory reagents, and some of the staff members might appropriate laboratory equipment.

Relative to costs, again taking Johns Hopkins as typical, the director said at the time of the erection of the 12 x 12 foot room: "I have carefully gone over the bills connected with the establishment of the laboratories . . . and find that $300.00 will fully equip such a laboratory." And then, with respect to maintenance: "Maintenance of a laboratory can well be accomplished on $50 a year."

In the past half century, every feature of the clinical pathological laboratory has changed to take on new proportions. Modern laboratory equipment is expensive and so is the maintenance of a laboratory. Particularly is the personnel a changed picture. In the American College of Surgeons' move to standardize hospitals, MacEachern indicated in 1925 that the hospital's efficiency depended on the role of the pathologist and hence on the clinical pathological laboratory. Medical practice has confirmed MacEachern's statement. The twenty-five years that have passed since this commitment have given proof that any doctor's efficiency is dependent on the availability of a reliable laboratory. During the first quarter

Sister Alcuin of the College of St. Scholastica, Duluth, Minnesota, is Chairman of the Public Relations Committee of the Minnesota Society of Medical Technologists.

of this century, while the tests were relatively simple and few, the physician could manage not only to get them done but even to interpret them. During the past twenty-five years, however, the field of the clinical laboratory has greatly broadened, and there has evolved the clinical pathologist. As pointed out in 1925 by John Kolmer, M.D., making the routine tests was not elevating clinical pathology to a specialty, any more than doing the work of a well-trained nurse was practicing medicine. So further evolution brought into being, as an auxiliary to pathology, the profession of medical technology and the medical technologist.

In the light of present-day understanding, what is medical technology? The poorly informed think it merely a transition from high school to being a helper in a doctor's office; others regard it as a transition from high school to being a nurse. It is neither. Medical technology is a profession in which the members learn and utilize the scientific principles that stem from the fields of chemistry, mathematics, physics and the biological sciences, principal of which are zoology, parasitology, bacteriology, anatomy, physiology, histology, hematology and immunology, to recognize facts helpful to the doctor in making a diagnosis.

Webster defines "profession" as an "open declaration," a "calling" or "vocation *especially not mechanical.*" Thus, medical technology is a calling—a natural desire to follow a walk of life that is scientific, more or less routine, demanding skill especially of the hands, an abundance of perseverance, and, as in fields of exertion, reasonably good physical health and mental and emotional soundness. A "technician" is often confused with a "technologist." A "technician" can be defined as "an operator of machines." A technologist has the "logus" as well as the ability to operate machines. More often than not a medical technologist still has to answer to "technician," "laboratory worker," "laboratory technician," "medical technician," all of which the properly trained medical technologist is not. Someone has said: "They call anybody from a psychiatric social worker to a medical stenographer a medical technologist." It is unfortunate, but this is true. Who is the medical technologist? She (he is the exception) is an individual, well versed in the scientific principles mentioned already, so that she can apply them to various technical procedures and uncover basic facts that aid the doctor directly or indirectly in the practice of medicine and medical research. The medical technologist is one who makes it possible to give the necessary services in chemistry, bacteriology, and the several other fields from which medicine draws without employing an identical number of specialties to handle adequately the respective sciences. In other words, it is she who creates somewhat of a paradox in science: more specializing with less specialists. This is the mid-century concept of the term medical technologist. Physicians now admit that their high esteem for the profession of medical technology comes from the reliance they can place on the help of the properly qualified medical technologist. They assume that the acquired data is carefully obtained, the realization of which the medical technologist is aware. It makes the medical technologist and physician co-partners in sharing the moral responsibility of the patient. Should a pathologist play a part in the service, then the medical technologist completes a trio, and her dignity lies in being entrusted with the professional responsibilities of both. This brings us to the current problem in medical technology, the second crisis in its history.

The first crisis in medical technology came immediately after the close of World War I, when in the rush to become standardized, hospitals, spurred on by the American College of Surgeons, set up clinical pathological laboratories in their institutions. A shortage of pathologists to direct them became apparent, but a greater shortage of laboratory assistants was still more apparent. Organization was established among the pathologists and about 1921, the American Society of Clinical Pathologists was created to be climaxed by the establishment of the Board of Pathology in 1935. Once the clinical pathologists were organized, they began to organize their assistants, then variously labelled but generally identified as laboratory technicians. This era with its scarcity of laboratory technicians was marked by chaos and confusion among them.

The second crisis in medical technology is the one we are experiencing now as the aftermath of World War II. It, too, is earmarked by a scarcity of medical technologists, and by confusion. This time, however, the confusion is not limited to the laboratory workers; it includes the public as well. The scarcity of medical technologists stems from the greater use of the clinical laboratory because of the effectiveness and accuracy of the laboratory in establishing diagnosis as demonstrated already in World War I but greatly emphasized in World War II. And the second of the principal reasons is that this is the generation of medical men trained to practice in terms of laboratory findings. In the first crisis, "schools" mushroomed into existence and, among others, substandard laboratory technicians appeared. The Registry of Medical Technologists of the American Society of Clinical Pathologists, to be described later, came to the rescue. It aimed to curb the training of laboratory technicians pretty much as the American Medical Association aimed to curb the "diploma mills" that turned out incompetent doctors, pharmacists, and the like.

Its story is this: In October, 1922, the first public pronouncement regarding the desirability of proper training and classification of medical technologists was made by a member of the Minnesota State Medical Association at the annual meeting of that Association. Six years later, while the American Society of Clinical Pathologists was nationally convened in Minneapolis, that earlier proposed plan of a "central control body" for medical technologists crystallized into what is now known as the Board of Registry of Medical Technologists of the American Society of Clinical Pathologists; in brief, the Registry (ASCP).

The Registry (ASCP) is a standardizing board in medical technology, being originally composed of six pathologists but since 1950 of nine members, the three additional being medical technologists certified originally by the Registry. After nearly a quarter century of operation the Board carries on practically the same now as when originally designed. Its purpose is to screen the unfit from attempting training for medical technology, and to closely watch the training of the accepted student as to school, curriculum, and quality of performance. Epitomizing the purpose of its existence, it is to ensure competent, ethically-trained and ethically-minded personnel for medical technology and to safeguard that profession. The quarter century of its existence has proven that it has fulfilled its purposes without political influence, or personal ambitions on the part of its personnel. It has operated purely on a voluntary basis. Those submitting to its jurisdiction have done so on their own volition. The plan of operation of the Registry has been so successful that it now enjoys the endorsement of the American Medical Association, the American College of Surgeons, the American Hospital Association, the Catholic Hospital Association, and leading educational institutions associated with medical schools and colleges, besides the American Society of Clinical Pathologists.

According to Registry standards, to hold a certificate from that agency the candidate must have met the minimum pre-technical and technical training requirements. The minimum pre-technical requirement consists of two years of college work following a prescribed curriculum, and the technical, twelve calendar months in an "approved school" of Medical Technology which now means a clinical laboratory endorsed for training medical technologists by the Council on Medical Education and Hospitals of the American Medical Association. However, most of the "approved schools" —and there are about 450—have minimum college requirements of their own consisting of at least three years of college work preceding the year's technical training, and all leading to a college degree. The final hurdle is the successful writing by the candidate of a nationally conducted examination, prepared or edited by a member of the Registry, administered by authorized proctors throughout the United States and machine scored by a salaried expert. This examination paper, together with the college transcript, the application blank properly endorsed, and other credentials remain filed in the Registrar's office of the Registry. The endorsement of the application blank bears subscription to a Code of Ethics promising among other things not to operate an independent clinical pathological laboratory nor otherwise commercialize his practice of medical technology. Certification is given the successful candidate in the form of a written document signed by the Registry officials and with the right to affix to his name the insignia M.T. (ASCP)—M.T. only before 1941.

The first insignia issued by the Registry was L.T., meaning laboratory technician, while a choice few were given M.T., but in 1936 a ruling went into effect that M.T. would be the only insignia. By 1941, it became necessary to differentiate medical technologists certified by the Registry (ASCP) and others. The following Registry notice of 1941 explains the issue:

Notice to Registered Medical Technologists Holding Certificates from the Registry . . . In order to differentiate the original M.T.s who hold a certificate from the Registry of Medical Technologists of the American Society of Clinical Pathologists from those who affix the same letters to their names and are thus trying to confuse the public, it is proposed that all those medical technologists who are identified with the Registry be urged to write after their M.T., ASCP in parenthesis, thus M.T. (ASCP) which clearly indicates that they are recognized by the American Society of Clinical Pathologists.

Registered medical technologists (ASCP) are entitled to protection from unwarranted intrusion of a group of technicians whom we think are not ethically entitled to the designation (M.T.) which by common usage and consent has been the property of the American Society of Clinical Pathologists for more than ten years.

When the Registry first proposed certification of medical technologists, 350 laboratory technicians applied for certification The number certified was small but with time increased rapidly so that in 1936 there were at least 3,500; by 1941, nearly 10,000, by 1945 nearly 12,000 and by 1951 nearly 20,000. For the 20,000 that are on the roster of the Registry it is safe to assume another 20,000 are not on that Registry roster. Some have never been enlightened about the Registry although qualified to register; others have been misinformed, and a third group of nonregistrants (ASCP) have objectives that are questionable. But with respect to all those outside of the Registry and the professional organization for its registrants it has been said: "At the expense of those who are registered (ASCP), those who are qualified and have not registered are no doubt reaping where they have not sowed."

The professional organization for medical technologists came into being June 13, 1933, at Chicago with a roster of some twenty members. It is known as the American Society of Medical Technologists, abbreviated, ASMT. It soon became a corporate body according to the statutes of the State of Michigan. In 1947, it was reorganized under a system similar to that of the American Medical Association and the American Nurses Association, in that constituent societies exist according to states, and district societies of medical technologists within the states. Under the new plan, it grew rapidly and is now approaching a membership of 10,000. The first editions of its official bimonthly organ known as *The Journal of Medical Technology,* appeared in early 1935. It is now in its seventeenth volume.

Through the concerted efforts of the professional organizations of the registered (ASCP) medical technologists, commissions have been obtained for qualified medical technologists in the United States army and air forces; civil service ratings have been adjusted in their favor and are spiralling toward a point equitable with their training; politics have been kept out of medical technology, licensure has been controlled, and medical technologists are gaining voice in the determination of their own policies.

The confusion characterizing in part this second crisis in medical technology has resulted from initial opposition to the Registry (ASCP) and its activities by groups which have since merged their interests and have grown into formidable organizations. In 1935 their representatives said of the Registry:

> The promised boycott in a few years of all technicians who fail to register in the Registry of Technicians and subscribe to its requirements in order to work in a hospital approved by the AMA is a threat. This is a minority move to coerce the technician and blind him so that he will not seek true standards.
>
> And recently they referred to what appears to be Registry policies as a "system of controlled dictatorship among hospitals and schools."

The first organization to make its appearance was the counterpart of the Registry known as the American Medical Technologists, the AMT. Then followed an organization to become the counterpart of the American Society of Medical Technologists, the ASMT. This second organization called itself the American College of Medical Technologists, the ACMT. For "approved schools," the counterpart became "accredited schools," and now the expressions: registration, registered medical technologist, examination, journal, code of ethics, and other parlance are used as glibly by those outside the recognized institutions as by those with whom such expressions originated. No attempt to protect themselves by law has been made by the Registry, or the ASMT save to become corporate bodies. No recourse has been had to legislation to protect objectives and terminology. Thus in 1940 the Journal of the American Medical Association review the activities up to that time:

> . . . Within the past six months one C. A. Bartholomew of Red Bank, N. J., who has never himself been registered, began to circularize the medical laboratory technicians of New England asking them for a fee of $5 to join the "American Medical Technologists" and offering to bestow the title M.T. by virtue of a charter from the state of New Jersey. As far as we know, this movement is not supported or authorized by any scientific body. The promoters seem, moreover, to have undertaken the task of passing on the competence of training schools for medical technologists. In this

they seem to be abetted by the proprietors of some commercial schools which have not themselves been approved by the Council on Medical Education and Hospitals and the Registry. This would seem to be the old technic of having one soiled hand wash the other. Graduates from these unapproved schools who are ineligible for the Registry's examination seem to be welcomed into the "American Medical Technologists." Indeed, a teacher of one of these schools has, it is reported, solicited its graduates to join this organization at reduced rates. Complaints have come to both the Council and the Registry against the efforts of this unauthorized and irresponsible body to undermine the scientific and ethical standards that have been set up for the practice of this important vocation by the American Medical Association and the American Society of Clinical Pathologists. Certainly physicians everywhere will do their utmost to inform young men and women who contemplate a career in medical technology of the hazard that lies in participation in such courses or organizations.—J.A.M.A., 114:1269-1270 (Mar.) 1940.

Recapitulation

The Recognized Institution	*Its Counterpart*
The registry (ASCP). Established and incorporated in Colorado in 1928. Operating out of Muncie, Indiana, under the chairmanship of Dr. Lall G. Montgomery.	The American Medical Technologists, AMT. Established in New Jersey about 1940. Operates out of Easthampton, Massachusetts, under the secretaryship of Mr. C. A. Bartholomew.
The American Society of Medical Technologists, ASMT, incorporated in Michigan and functioning since 1933.	The American College of Medical Technologists, the ACMT, established and incorporated in New Jersey in 1942.
"Approved Schools"—approved by the Council on Medical Education and Hospitals of the AMA.	"Accredited schools"—accredited by the Council on Education, Qualifications, and Standards of the American College of Medical Technologists.

The American Medical Technologists, created a decade after authorized organizations became accepted entities, and the American College of Medical Technologists, also a decade too late to be the authorized one, are interrelated and interdependent organizations. The members of both call themselves registered medical technologists but the whole regimen is autonomous—these "registered medical technologists" set their own standards, give their own examination, issue their own certification, work under a Code of Ethics which permits them to operate independent laboratories, without the direct supervision of a doctor of medicine. Contrast this with the manner in which medical technologists (ASCP) conduct themselves. They have worked with considerable dependence on the medical doctors but are gaining their autonomy in proportion to the merits they manifest. They are conscious of the need of the protection of the medical profession—they are the personnel that have come into the sheepfold by the right path. They hope only to serve medicine ethically. They have their rights and privileges but they also assume their responsibilities. Now their rights and privileges are to have the sanction of the medical profession in gaining recruits, in establishing a gradation of preparation, in establishing institutions for training at various levels in the profession, and in soliciting the discriminating eye of the medical man in employment. It is no longer enough to ask: Are you registered? but, Are you registered ASCP? There is a difference.

Minnesota was the first state in the union to inaugurate a collegiate course in medical technology. This course was instituted at the University of Minnesota in 1923. Minnesota is the only state in the world that has all its approved schools on the collegiate basis leading to a bachelor's degree with a major in medical technology, or the degree wholly in medical technology. These schools are the University of Minnesota; Minneapolis General and Ancker Hospitals affiliated with the University of Minnesota; the Chas. T. Miller Hospital affiliated with Macalester College, Saint Paul; the Swedish Hospital, Minneapolis, with Gustavus Adolphus College, St. Peter; St. Luke's Hospital, Duluth, with Hamline University (originally, but admits students from other institutions of higher learning); St. Mary's Hospital, Duluth, with the College of St. Scholastica; and St. Cloud Hospital, St. Cloud, with St. Benedict's College. Minnesota stands first in having the school with the largest enrollment in medical technology in the world. This is the University of Minnesota which annually averages some fifty graduates. Lastly, Minnesota is the leading state in the nation for organization and activity among its medical technologists of which there are about 240 M.T.s (ASCP)

The state organization of medical technologists

ACUTE LARYNGOTRACHEOBRONCHITIS

F. G. FOLKEN, M.D.
Albert Lea, Minnesota

ACUTE laryngotracheobronchitis is a clinical entity occurring in infants and young children but which has only been recognized as such during the past decade or so. It may occur epidemically.[14] The disease is rarely seen in adults, the almost universal incidence in children being explained by the fact that the infantile larynx is especially susceptible to reflex spasm, is much less rigid and more easily collapsible than in adults, and there is much more inflammatory edema in proportion to the diameter of the lumen, the airway being diminished considerably more than in adults. Children also have a lower immunity to respiratory diseases.[13] The condition is frequently unrecognized or inadequately treated as a laryngitis, tracheitis, bronchitis, or common cold but is actually a serious, prostrating and sometimes fatal disease.

The etiology is unknown but there is usually a mixed infection, two or more types of bacilli commonly being involved and accounting for the frequently overwhelming infection and toxemia. Hemolytic streptococci, streptococci viridans, staphylococci, pneumococci, influenzal bacilli, or Friedlander's bacilli may be present. Some cases appear of viral origin.[13] Some believe that a preliminary virus infection paves the way for a pyogenic invasion.[2] An ulcerative tracheobronchitis may complicate a typical pneumonia.[7] Emery[4] reports that, in a series of 332 cases, many of the children were what the layman usually considers a healthy child—overfed, overweight, with red cheeks and fat thick limbs. These babies were so often admitted to the hospital the following winter with croup that this condition was often called the "croup physique." His observation indicated that laryngotracheobronchitis occurs more frequently and with greater severity in overweight children. The condition is a cold weather disease, the incidence being much greater with sudden weather changes than with continued cold. This is believed to be partly a result of the suddenly increased heat and lowered humidity in houses. Nasal catarrh develops; and the consequent mouth breathing, by permitting the dry air to impinge directly upon the larynx without being previously moistened in the nasal passage, produces a dry, scratchy throat especially susceptible to bacterial invasion.

Pathologically, the disease is an acute infection of the larynx, trachea and entire bronchial tree. The pharynx may also be involved in severe cases. The mucosa and wall of the larynx, trachea, bronchi and bronchioles are acutely inflamed, swollen and edematous. The vocal cords are red and edematous. Thick, viscid pus may be seen oozing out between them. A purulent, sticky, gummy secretion forms and may fill the entire lumen of the trachea and bronchi down to the finer ramifications. Scattered patches of atelectasis, congestion and consolidation may be found in the lungs at autopsy and a purulent exudate squeezed from their cut surfaces.

The onset of the disease is usually abrupt in an infant who has been in contact with another child or an adult having an upper respiratory infection. An afebrile acute rhinitis and pharyngitis develops and is accompanied by a dry, croupy cough. After a few hours or days, the temperature suddenly rises and severe respiratory symptoms develop. The child becomes hoarse, develops an inspiratory crow, and expiratory wheeze and may become seriously dyspneic. There may be extreme toxemia and prostration. There is a characteristic inspiratory retraction of the suprasternal and infrasternal notches, the intercostal spaces and the epigastrium. Progressive restlessness and cyanosis develop as a result of the anoxemia. Cough is constant but usually unproductive even in older children because of the thick secretion. Dehydration, prostration and finally complete and usually fatal collapse develop, the child being in an anoxic coma with its entire energy spent in breathing.

Physical signs are not diagnostic except for the inspiratory crow. Physical examinations show the conditions just described and should be minimized. Moist râles are common. Fine, sticky râles indicate alveolar involvement but the inspiratory stridor often obscures breath sounds.

Read before the Minnesota Academy of Ophthalmology and Otolaryngology, March 25, 1952.

Absent breath sounds and impaired percussion resonance indicate areas of atelectasis. Laboratory findings are not helpful diagnostically, and pulmonary roentgenograms only show the presence of some pulmonary complication. Bronchoscopic examination shows an inflamed and edematous larynx with only a small posterior opening between the cords. The trachea is found to be inflamed, edematous and filled with a thick, gummy mucus which may rapidly dry into crusts obstructing the trachea or main bronchi.

Laryngeal diphtheria is the only condition closely resembling acute laryngotracheobronchitis and can usually be eliminated by throat smears, cultures and laryngoscopic examination. Laryngotracheobronchitis is differentiated from simple spasmodic croup by the persistence of symptoms after the usual palliative treatment. Location of the obstruction is indicated by the degree of recession of the soft parts; the greater the retraction, the higher the obstruction. Inhalation of a foreign body is differentiated by the history, auscultation and chest fluoroscopic examination or roentgenograms. The diagnosis is based upon recognition of the presence of obstructive dyspnea and a serious emergency. It should be obvious with the advent of increasing dyspnea, restlessness, fever and cyanosis. The prognosis is always serious, there being almost 100 per cent mortality in untreated cases, 70 per cent in those partially treated, and 9.2 per cent at best.[4,8,13] The age group has been found important prognostically, the highest incidence of the disease being in children about two years old and 87 per cent of all deaths in those under four years of age. About 65 per cent of patients are males.[15]

It may be difficult to decide whether the child should be treated at home or hospitalized. The latter is best, as proper treatment can only be provided in a well-equipped hospital. If home treatment is attempted, the patient should be promptly hospitalized if the condition does not improve in a few hours, if the cry is hoarse or husky, or if there is evident retraction about the chest. Apparent relief after vomiting is often only temporary, the child soon becoming worse.

Treatment is based upon the etiology and pathology of the disease. Infection must be combated, secretions loosened and removed, and supportive measures provided. A humid atmosphere of steam is essential to thin the thick secretions, the room temperature being kept as near normal as possible. A steam tent or room is usually best, two or three steam kettles generally being necessary. Mechanical humidifiers in an ordinary room are preferable if available, as they provide moisture without making the room uncomfortably hot. The appearance of cyanosis indicates a need for oxygen. This should be well moistened when used as it otherwise causes the respiratory secretions to become undesirably dry. It is best given in an open top tent. Weinstein[15] recommends the use of humidified cool oxygen in place of the steam croup tent, and a helium-oxygen mixture instead of straight oxygen. Many strongly feel that sedation should not be used,[10] but it may be necessary for children who are easily frightened. It must be carefully administered because of the danger of unduly suppressing the cough reflex and respiratory rate. Small doses of phenobarbital are preferred if sedation is necessary.[4] Codeine sulphate should not be used as it increases the viscosity of the sputum. Antihistaminic drugs are contraindicated.

Secretions may be liquefied by the use of calcidine gr. ii or five drops of a saturated solution of sodium iodide three times a day to a two-year-old child and three drops to a patient one year old. Because of the efficacy of carbon dioxide in liquefying bronchial secretions, the use of a 2.5 to 4 per cent mixture of this gas with 20 per cent oxygen in a tent has been suggested.[10] Expectorants are not recommended for general use though ipecac in emetic doses may sometimes be helpful.[4] Frothy or mucoid secretions in the nasopharynx or throat should be gently suctioned out. James[6] reported dramatic results from the use of atropine sulphate gr. 1/400 subcutaneously every three hours in four infants extremely ill with acute tracheobronchitis and who had not responded to treatment with penicillin or sulfadiazine. Improvement was immediate, sputum diminishing, breathing becoming easier and the cyanosis disappearing. One less seriously ill child responded similarly to Tr. belladonna by mouth. The atropine injections were continued until all crepitations had disappeared from the chest. Lamont[8] and Logan advise against the use of atropine sulphate in these cases, however, as it increases the viscosity of the sputum.

Hydration is most important. Fluid should be given subcutaneously or intravenously if it cannot be taken by mouth, at least 60 cc. per pound of body weight being given infants every twenty-four hours. Older children require about 30 cc. per pound. One or more blood transfusions of 100 to 150 cc. each may be necessary to combat infection and support the patient. Logan[10] states that the use of concentrated blood plasma or blood serum for its dehydrating effect upon laryngeal edema has not been effective. Nutrition should be maintained, food being given as desired and usually in liquid form. Throat cultures are important, material being obtained by a suction apparatus.

Vigorous chemotherapy or antibiotic treatment is most important but varies with the case, depending upon the etiologic bacterial organism. Time cannot be taken to isolate it however. Immediate combined treatment with penicillin, streptomycin and aureomycin or chloromycetin should therefore be started.[4] Sulfonamide drugs are still valuable treatment aids, sulfadiazine being preferable, but the three mentioned antibiotics will control practically all bacteria which may be present without causing possible urinary complications. Penicillin should be given intramuscularly every two or three hours or continuously in a vein. Recommended dosage for a two-year-old child is 200,000 units divided into eight doses daily. Penicillin may also be given in large doses orally. Streptomycin in doses of 0.8 to 1.0 gm. daily, divided into four to eight doses, has been quite effective against the Hemophilus influenzae. A daily dose of 0.5 gm. is sufficient for a one-year-old infant. Moncrieff and Weller[12] report excellent results following the administration of chloromycetin 0.25 gm. three times a day for four days, starting a few hours after tracheotomy. About eight hours is usually required to obtain adequate blood levels from antibiotics to produce improvement. Cortisone 60 to 80 mg. intramuscularly q 8 hrs. has been used on recent cases and undoubtedly shortens the period of recovery.

Tracheotomy is indicated if the child has not improved one hour after admission to hospital,[13] or if the dyspnea increases and laryngeal obstruction becomes more marked in spite of treatment. It should preferably be done by trained operators. Some patients are so seriously ill upon admission that immediate tracheotomy is indicated. Extreme restlessness, cyanosis and fatigue also indicate tracheotomy. This operation is preferred to intubation and is best done after a preliminary bronchoscopic examination and sucking out crusts and secretions. Intubation and laryngeal suction only relieve upper obstruction and do not affect the inflammatory swelling or secretion in the trachea or bronchi. Aspiration can only be done intermittently by bronchoscope. Care must be exercised to so place the incision that the tracheotomy will not irritate the subglottal region.[10] Delayed tracheotomy increases the likelihood of pneumonia. Special day and night nurses are advisable before tracheotomy and imperative afterwards. The high reported mortality after tracheotomy in these cases can be avoided by careful postoperative treatment. It is generally agreed that the operation should be done over a bronchoscope or other laryngeal airway. The air entering the tracheotomy tube after operation must be kept moist to help prevent the formation of crusts in the trachea, the same methods being used after operation as before. Albers[1] reports most satisfactory results from the use of a nebulizer attached to a rubber tube carrying oxygen, the lower end being applied to the tracheotomy opening by a flexible rubber hose. A small rubber nipple with the teat cut off has also been satisfactory for this puropse and even life saving.[10] The bronchoscope should not be inserted more than 2.5 cm. beyond the cords. The suction catheter should be used frequently and freely. This is contrary to most authorities. Their advice is not to insert the catheter beyond the end of the tracheotomy tube. Moist saline compresses over the tracheotomy tube, injection of steam into the oxygen tent, or the periodic instillation of a few drops of saline or warm mineral oil into the tube may all be tried.

The early recognition of acute laryngotracheobronchitis and elective treatment rather than emergency efforts to relieve terminal asphyxia greatly increase the probability of obtaining satisfactory results from treatment.

Case Report

G. K., aged three, was hospitalized on January 11, 1948, because of labored breathing with intermittent cyanosis, hoarseness, elevated temperature, and a general toxic appearance. Five days prior to entering the hospital the child developed nausea and vomiting and a low grade fever. The following day he had a moderate diarrhea. Examination in the office by the family physician revealed slight injection of the pharynx; there was a slight cough, the abdomen was slightly tender, temperature was 99.4°, pulse 100, respirations 22, and no pulmonary involvement existed.

In the following thirty-six hours he seemed to be normal except for a slight cough. That evening he developed a hoarseness, and the temperature was 101°. Steam inhalation and a cough medicine (cheracol) seemed to give relief until 2:00 a.m., when he developed a persistent dry hoarse cough; the temperature was 102.4° and the breathing was more rapid and heavy. He was again seen by his physician at 11:00 a.m. At this time the child was listless and appeared toxic. His temperature was 102.4°, pulse 100, respirations 28; his voice was husky, the pharyngeal mucosa was injected with some mucoid exudate on the posterior wall, and a definite stridor existed over the laryngeal tracheal area which obscured other chest sounds. Penicillin 300,000 units was given intramuscularly. At 1:45 p.m. the mother reported that the child had grown worse and at times was gasping for breath. Immediate hospitalization was advised and carried out.

At the time of entry the child had a temperature of 102°, pulse 140 and respirations 38. He was well nourished but had a definite toxic and fatigued appearance, laboring desperately to obtain air.

Diagnosis: Acute laryngeal tracheal bronchitis.

Tracheotomy was immediately performed but under difficulty. The trachea had collapsed due to cessation of breathing. Aspiration via the tracheal opening expressed a large amount of heavy purulent mucus and breathing was restored by artificial respiration and the use of oxygen.

Postoperative treatment consisted of penicillin, streptomycin and calcidine therapy, room humidifiers, frequent cleansing of the inner tracheotomy tube, repeated suction via rubber catheter inserted through the outer tracheotomy tube and the constant attention of trained nurses.

Recovery was at times rather stormy but rapid and complete. The tracheotomy tube was removed on the fifth postoperative day and the patient was dismissed from the hospital on the eighth day. The tracheal wound had closed with the exception of the overlying skin. Breathing was free and normal, and the voice was clear and distinct.

Comment

This case was chosen as the most typical one of twenty-eight patients seen by me during the past four years, all requiring tracheotomy except six. There were three deaths. Two occurred postoperatively, and one in a patient in whom tracheotomy had been performed after breathing had stopped while on the way to the operating room. The child could not be revived by artificial respiration, the use of stimulants or oxygen.

Each case is a distinct problem in itself. Some patients take on a rather uneventful course and require only a moderate amount of attention. This is usually true in patients who have not reached the desperate stage prior to operation. Others present little time for operative procedure because of their critical condition and therefore not only make the operation more difficult but also have a more stormy convalescence, requiring more intensive nursing care and intravenous and subcutaneous treatment to combat the infection and dehydration.

ROUTINE CHEST EXAMINATIONS IN A PRIVATE GENERAL HOSPITAL

J. P. MEDELMAN, M.D., and JOHN F. BRIGGS, M.D.
Saint Paul, Minnesota

IN NOVEMBER, 1950, a program was instituted calling for routine roentgen examination of the chests of all persons admitted to St. Joseph's Hospital in Saint Paul. This report is prepared in the belief that our experiences, reviewed after one year of operation of the plan, will be of interest and of value to other groups and individuals concerned with such programs.

The need and benefits of chest surveys, in general, and for hospitalized persons, in particular, are generally accepted. Prior to the institution of the routine examination at St. Joseph's Hospital, an intern and a nurse, who previously had negative tuberculin reactions, became seriously infected with pulmonary tuberculosis during one year. Both recovered after prolonged treatment but the experience proved to the hospital authorities the great responsibility of discovering infectious tuberculosis in patients admitted to the institution. The next requirement was to interest the hospital staff in the project. Both of us were deeply concerned with the problem. We arranged a staff meeting at which Dr. Jay A. Myers of Minneapolis discussed the importance of the procedure. It had been anticipated that the staff physicians of the hospital might object to the plan on the grounds of generally high hospital costs. However, there was a very favorable reaction to Dr. Myer's speech. In general, the staff supported the proposal to x-ray the chests of all persons admitted.

St. Joseph's Hospital has approximately 10,000 admissions yearly, exclusive of the pediatric service. It was decided that a survey for detection of pulmonary disease could be best accomplished by photofluorograms rather than standard sized films. It was further decided that 4 by 5 inch film best meets the necessary compromise between cost and diagnostic reliability. Incidentally, films of this size are easy to process, do not take unreasonably large filing space and are readily available for future study after filing. Previous experience by one of us (J.P.M.) had shown that the photoroentgen machines routinely offered by the manufacturers were not entirely satisfactory for examinations of all patients. A 300 milliampere transformer was specified when ordering the unit, in contrast to the 200 milliampere transformer ordinarily furnished. The results have been better than expected not only for large patients, difficult to radiograph, but also for average individuals. The exposure time can be made short in all cases, as an abundance of electrical power is available.

The photoroentgen unit at St. Joseph's Hospital is located about 150 feet from the admitting office. We feel very strongly that even this short distance is a distinct disadvantage in that it reduces the number of admission films obtained. Ideally, the unit should be adjacent to the admitting office or, even better, should be directly connected with that office. A compromise must be made in existing plants. New hospital buildings of 150-bed capacity or more should be planned with space available to the admission department for a photoroentgen unit. Smaller institutions might be better off by making 14 by 17 inch roentgenograms in the established roentgen department. Here, too, plans must be made for the additional load on the department.

The St. Joseph's Hospital unit is installed on the same floor as the admitting office, in a room formerly used for patients' beds. The room is large enough to accommodate carts and wheelchairs. Dressing rooms are not necessary, as we have never encountered any serious difficulty in making the examination with the patients clothed. We do not have a waiting room for the unit, but a small one would be desirable. This could well be used as a conference room except between the hours of 3 to 5 P.M. when most hospital admissions take place. These are the only hours when there is any appreciable delay in caring for patients at the photoroentgen room.

We felt, and still do, that processing of the films can best be done in the regular roentgen department. This eliminates the necessity of providing space for a separate darkroom for the unit. In addition, it is much cheaper to purchase a sufficient number of cassettes and hangers to last for a twenty-four-hour period than it is to install processing facilities near the photoroentgen unit separate from the Department of Roentgenology.

The staff to handle the unit is not a self-sustaining one. That is, our staff does not have the facilities for handling films and records for round-the-clock operation. It does not seem that there is any private hospital in Minnesota of sufficient size to justify such a complete staff from the financial point of view nor should such a staff be necessary from the standpoint of efficiency. St. Joseph's Hospital employs, on an hourly basis, student technicians to operate the unit from 2 to 6 P.M. each day. During the remainder of the time, the admitting office personnel is responsible for the procedure. It is essential that someone, adequately trained, be available to make examinations at all hours of the day and night. One must constantly impress upon all people concerned, the importance of striving to examine every patient admitted in order that the whole program may be successful.

During the first year of operation, 9,745 hospital patients, exclusive of pediatric patients, were admitted and 6,292 patients had routine admission films. Routinely examined were only 65 per cent of admissions, but the showing is not as poor as it seems at first glance. Patients admitted with orders for chest x-rays do not get routine examinations. Also, patients who have had chest examinations within six months previous to admission are not required to be again examined. By checking records, we found that for the month of July, 1951, chosen arbitrarily, 92 per cent of the patients admitted had either photofluorograms or standard roentgen examinations made of the chest. In January, 1951, chosen because the program was just getting under way, 70 per cent of the patients had chest x-rays of some kind. Our greatest difficulty comes in seeing to it that obstetric patients and those injured in any degree receive the routine examination. Such persons are frequently admitted under trying circumstances.

It is very difficult to get a routine examination once the patient has been admitted. The technician on duty checks with each floor daily. An attempt is made to get unexamined patients sent to the unit. Our percentage of patients examined proves this attempt is not too successful. However, we feel certain that the results will improve as time goes on and more of the hospital personnel become educated to the importance of the plan.

The patient is taken by the admitting clerks to the photoroentgen room before being taken to his hospital room. There is seldom sufficient delay to make this a hardship. The films are developed during the evening by the x-ray technician on emergency call. Roentgenograms taken during the night are developed at 7 A.M. when the regular work of the roentgen department begins. In this way, all roentgenograms are ready for reading early in the morning and we try to have the reports on the charts by 9:30 A.M. The films are filed by hospital number in the x-ray department in specially adapted cabinets. Duplicate reports, 4 by 5 inches in size, are filed with the films and the original is sent to the floor where it is glued to the first sheet of the chart. As a time saver, rubber stamps showing the most common findings have been made up. These findings are stamped directly on the filed film and on the report which goes to the chart.

This record keeping is admittedly simple. Such simplicity accomplishes saving of money, time and personnel. However, it does reduce the research and teaching value of the project. We believe that these functions should be left primarily to subsidized hospitals or individuals whether they be subsidized by public or private funds. Institutions depending for their support upon private fees are obligated to use those fees for private benefits. An elaborate system would also be necessary if the private hospital were to become engaged in a large-scale follow-up program. The primary reason for routine admission films is to protect patients and employes from infectious tuberculosis. Photoroentgen units function only secondarily as diagnostic setups.

The hospital, because of its responsibility to its patients and employes, does have the right to see to it that infectious tuberculosis is recognized or ruled out in any given chest lesion. It also has the right to insist that any necessary precautions be carried out when infectious tuberculosis is discovered. Beyond that, the individual members of the staff and medical organizations at the staff level and upward are responsible for subsequent diagnosis, observation and treatment of patients having lesions which are noninfectious. We do not believe that a long range follow-up system is the responsibility of a private general hospital.

We do think that the records should be available to qualified individuals or organizations who are responsible for such follow-up.

The patients are charged $1.50 for the service. This was agreed upon by the roentgen department and the hospital administration at the outset and has subsequently been approved by the Minnesota Radiological Society. We feel that there should not be a profit but that the activity should be self-supporting. A profit would probably defeat the purpose of the survey. On the other hand, the findings are of sufficient value to the individual to make it worth his while to underwrite his share of the money and effort expended by those responsible for the project.

Incidentally, a few staff members objected to the institution of this program on the grounds that it was a step in the direction of socialization. Our answer is that we, as private physicians and hospitals, are running this show and that public health authorities are not taking work from us or shoving the procedure down our throats. Actually, we are forestalling such steps. The appearance of public health authorities in this and similar activities is bemoaned by many physicians who, at the same time, fail to take advantage of the progress offered to them by the medical profession. Their lack of interest and inertia allows them to fall behind in following modern methods. They are not aware of the diagnoses they are missing and the good they may do their patients.

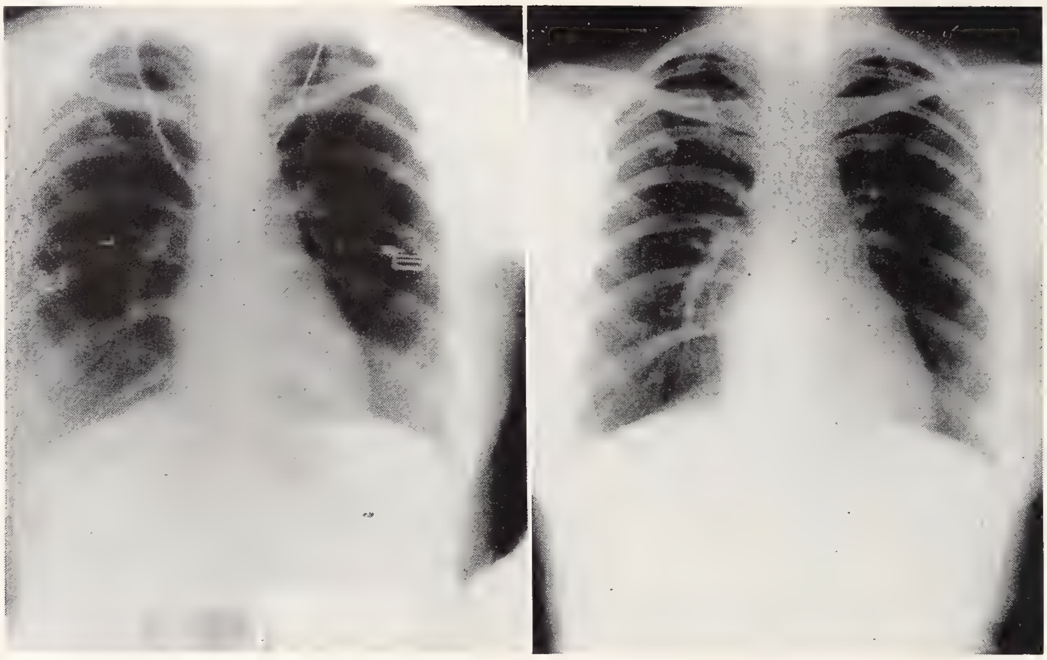

Fig. 1. *(a)* Photofluorogram showing apparently rather large lesion in right lung at level of 1st and 2nd interspaces anteriorly. *(b)* Standard sized film of the same individual showing insignificant lesion which had not changed over several years.

Anyone experienced in the interpretation of standard chest roentgenograms, will have little difficulty in dealing with photofluorograms. This is due to the character of the films which magnify findings and to the desire on the part of the interpreter never to miss a lesion. Actually, I believe that there is no more, and probably less, chance of missing a small lesion than on 14 by 17-inch films. Some roentgenologists state that they are willing to use 4 by 5-inch films for diagnoses rather than simply for screening but we believe these roentgenologists are overenthusiastic. The comparison is somewhat similar to the familiar one of the relative merits of a good little man versus a good big man (Fig. 1).

Many recheck films taken with standard methods turn out to show no lesions or insignificant findings. Never should a lesion prove to be tuberculous that had previously been interpreted as non-tuberculous on the photofluorogram. A definite diagnosis should be made from the miniature film only in very typical cases (Figs. 2 and 3). Abnormalities of the cardiac shadow are frequently under-read. Photofluorograms distort the heart outline slightly because of the shorter target-patient distance and there seems to be an insurmountable tendency to overestimate this distortion in interpretation.

In addition to the primary purpose of the survey, namely—to discover infectious tuberculosis, there are certain other advantages noted. Observation of the chest often provides a shortcut to the final diagnosis even in the absence of pulmonary symptoms. We believe routine chest examination is as important in the detection of disease as routine urinalyses and blood counts. For instance, the discovery of a tumor of the lung may eliminate many diagnostic studies. Bron-

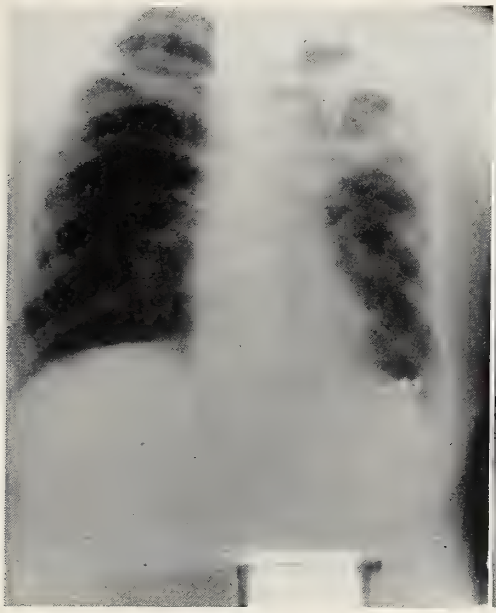

Fig. 2. Photofluorogram showing tuberculous cavity, clinically unsuspected, in a patient admitted for regulation of diabetes. This was the only roentgen examination made and the patient was admitted to a sanatorium within twenty-four hours of admission to St. Joseph's Hospital. Tubercle bacilli were found on the first sputum examination.

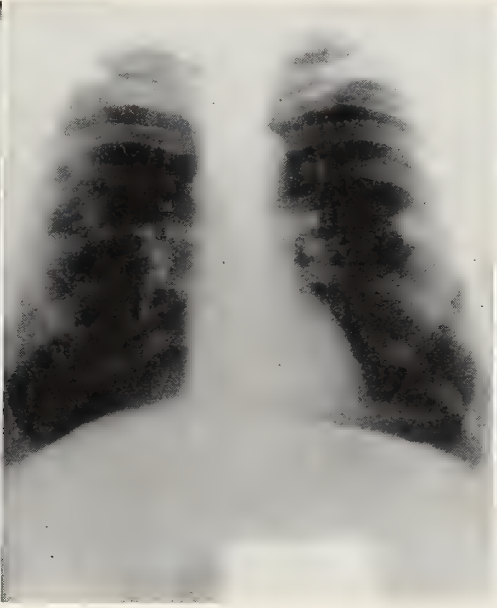

Fig. 3. Photofluorogram showing bilateral pulmonary metastases. The patient had carcinoma of the stomach.

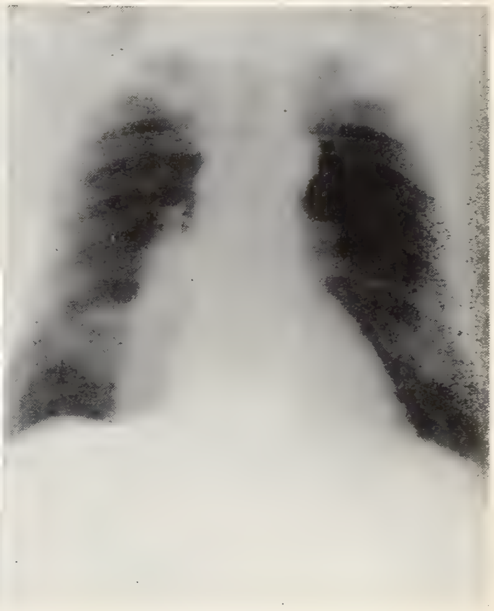

Fig. 4. Photofluorogram of patient admitted for cholecystectomy. Density to right of heart subsequently shown to be dilated esophagus due to cardiospasm. Patient well compensated for this lesion but precautions were taken to prevent aspiration of esophageal content at operation.

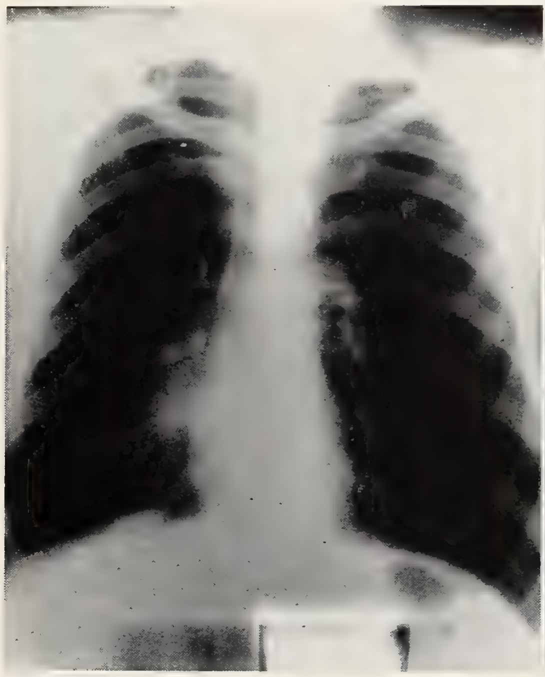

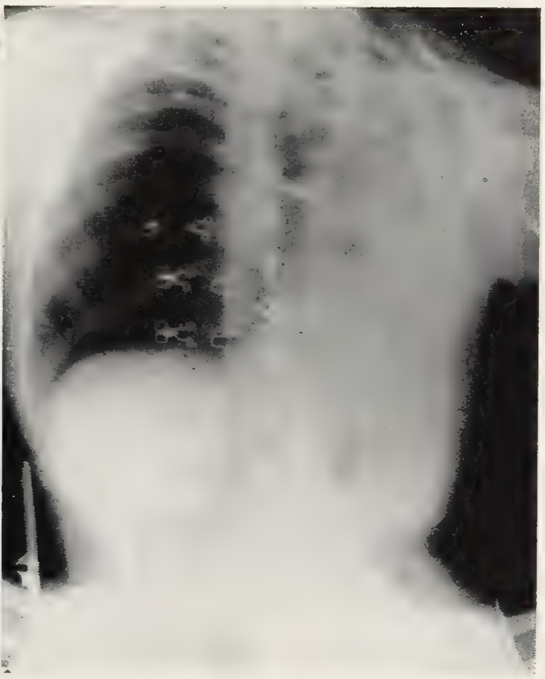

Fig. 5. *(left)* Photofluorogram showing carcinoma at right hilus.
Fig. 6. *(right)* Photofluorogram showing clinically unsuspected atelectasis of the left lung due to tuberculosis in a patient admitted because of uterine bleeding.

chiectasis with complete collapse of a lower lobe was found in a young patient admitted as a rheumatic fever suspect. Discovery of pertinent findings not related to the reason for hospitalization may be made (Fig. 4). The total time of hospitalization is frequently reduced by more speedy diagnoses. This is an advantage both to the patient and to the hospital which tries to render service to as many individuals in the community as possible.

There is an appreciable financial saving to the hospital by use of miniature films in routine employe and nursing staff checkups. Practically all private hospitals have at least yearly roentgenograms made of the chests of all persons working at the institution. Considering the film alone, several hundred dollars are saved annually by the use of photoroentgen methods in sizable establishments. Such methods are perfectly adequate for this work. This is true because the miniature film is a screening device and not a diagnostic tool.

In conclusion, we would like to present in Table I a summary of the results of the first year of operation of a photoroentgen unit in a moderate sized private general hospital.

TABLE I

Tuberculosis	
Patients now undergoing active treatment	10
Patients with reinfection type, significance undetermined	200
Tumors	
Primary, including lymphoblastoma	9
Metastatic	8
Cardiac Abnormalities	
Excluding left ventricular enlargement	136
Aortic Abnormalities	76
Pleural Effusion (non-tuberculous)	14
Pneumonia	49
Mediastinal Lesions	
Other than Lymphoblastoma	4
Diaphragmatic Lesions	
Excluding adhesions	10
Pulmonary Cyst	1
Pneumothorax (spontaneous)	3
Pleural Thickening	64
Atelectasis (mostly disc-like)	37
Others, rib-fractures, rib anomalies, scoliosis, etc.	
Of doubtful or no significance	236
Lesions noted on films but not followed in hospital	81
Total Lesions Found	848

MEDICAL MOTION PICTURES

UTERINE CANCER: THE PROBLEM OF EARLY DIAGNOSIS: 16 mm., color, sound, showing time 21 minutes. Sponsored by the American Cancer Society and the National Cancer Institute. Produced in 1951 by Audio Productions, Inc., New York. Procurable on purchase from the American Cancer Society, 47 Beaver Street, New York, or on loan from state cancer societies and state health departments.

The incidence of cancer of various sites in the female genital tract (International Classification) is given, with survival rates indicated for each. Symptomatology and aids in diagnosis are visually presented in animated drawings for each stage of cervical cancer, including stage O. The role of cytology in early detection is stressed, its technique visually described, and diagnostic criteria illustrated. Dr. Papanicolaou sounds a note of caution in using the method in diagnosis, by indicating that a positive smear should be confirmed as a matter of routine by biopsy and tissue diagnosis. The Schiller test and methods of biopsy are included.

The film calls attention to the importance of a complete physical examination, bimanual examination, visual inspection of the cervix, rectal examination, and aspiration of the cul de sac, together with this very simple method of securing cells from the cervical canal. Several case reports are shown to illustrate these points. It is presented entirely from the standpoint of early diagnosis of uterine malignancy. It does not include a discussion of treatment. The picture is well organized. The photography, animation, and narration are excellent, and the film is highly recommended for the general practitioner, the advanced medical student, and hospital meetings.—*J.A.M.A.,* Feb. 2, 1952.

President's Letter

MEETING OF THE YEAR

If membership in the Minnesota State Medical Association offered only one advantage—the opportunity to attend and participate in the annual scientific program and convention, I am certain that the membership rolls of the Association would not suffer any appreciable loss.

In this three-day session, Minnesota physicians are provided with an intensive and extensive survey of medical and surgical developments—this by way of lectures, symposia, round-table discussions, demonstrations and exhibits. They are afforded the chance to assist in shaping organizational policies and programs. This meeting often serves as an annual renewal of friendships which often lapse during the year under the pressure of distance and busy schedules.

This year the meeting is scheduled for Minneapolis. On May 26, 27 and 28, a substantial number of the state's physicians will be found at the Minneapolis Auditorium, absorbed in consideration and evaluation of medical advances.

The Radisson Hotel will be convention headquarters, with special luncheon and dinner meetings slated for the Radisson and other nearby meeting places. The annual banquet this year, on Tuesday night as always, brings an outstanding speaker, Dr. John Fulton, of the medical history department, Yale University, who will speak informatively, but amusingly, on "Rabelais and Modern Medicine." The Distinguished Service Medal, Fifty Club membership certificates and the Southern Minnesota Medical Society medal will be presented at the banquet.

The Hennepin County Medical Society will entertain at an open house program Monday night, and there will be the customary choice of outdoor sports and other entertainment during the convention.

The scientific program will attain an exceptionally high level of interest and information, and I am sure that no member of the Association will want to forego the privilege of attending.

Roger L J Kennedy

MEDICAL EDUCATION ASSISTANCE

TO THOSE who have given the financial dilemma of the medical schools of the country due thought, it seems highly essential that the schools be kept financially independent of federal support. The American Medical Education Foundation has been established for the purpose of providing financial assistance for medical schools, both those privately and state supported.

It is believed that the millions of dollars needed yearly by the medical schools, in addition to their present sources of income, can be raised with a little co-operation on the part of the variously interested parties. It has been pointed out that each medical graduate has paid in tuition for about an eighth of the cost of his medical education. It would be rather difficult to refute the argument that each physician today is in debt to his alma mater to the tune of several thousand dollars. If 100,000 physicians were to contribute 100 dollars each to the support of his alma mater, the total of ten million collected would solve the problem. Many cannot make this annual repayment, but on the other hand the majority can. The realization of the need and the justice of the request is essential, and that is the function of the American Medical Education Foundation.

The American Medical Education Foundation published the first issue of *The Foundation* in February, 1952. Its purpose is to broadcast information about the Foundation's activities, and future issues will appear from time to time. The campaign for raising funds for 1952 began April 1 and will continue until June 30.

The Foundation, in 1951, raised some $745,000 from 1,811 individual physicians, 33 organizations and 33 lay friends. While the total was far short of the goal set, the result is not too discouraging for the organization's first year of existence. When it is considered that, of the total, $500,000 was contributed by the AMA and $100,000 by the California State Medical Association, it is evident that comparatively few physicians contributed individually. Doubtless, a much better showing will be made in 1952.

It seems appropriate that other State Medical Associations should follow the lead of the California State Medical Association which with a 11,000 membership contributed $100,000 and South Carolina which with a 1,100 membership sent in $10,000 to the Foundation.

A further means of providing a substantial support for the Foundation was suggested by Dr. John W. Cline, AMA president, at the annual Congress on Medical Education and Licensure held in Chicago in February. The AMA Trustees approved, in principle, a plan whereby the AMA as a corporation would accept patents for medical discoveries made by member physicians. Royalty would be turned over to the Foundation for distribution to medical schools.

It is of interest that a new method for distributing the Foundation money has been adopted. Gifts made in 1952 may be designated for a specific medical school whether it is privately endowed or state supported. Such earmarked contributions will be added to that medical school's share of undesignated gifts. Thus, an alumnus may be sure that his contribution will go to his alma mater. In addition, in order to eliminate possible competition with fund-raising campaigns of the individual medical schools, the Foundation will give appropriate recognition in its annual report to those physicians who made gifts directly to a medical school.

The medical schools are not dependent entirely on the medical profession for the solution of their financial difficulties. Eleven states in the South contributed $1,091,500 to a common fund for the use of medical schools in the South. A similar plan is under way for eleven states in the West. The legislatures of five states, Colorado, Montana, New Mexico and Oregon, have already approved the plan, and it is expected the other six will follow suit. This seems like a much more reasonable solution than to use federal funds, collected in the states, sent to Washington and only in part returned to the medical schools of the states.

We have made previous editorial mention of the National Fund for Medical Education which has been established with the sponsorship of industry, pharmaceutical houses, organized labor, agriculture, scientific and educational foundations to which contributions to the American Medical Education Foundation are funneled.

The co-operation of the various interests mentioned could well provide the funds required to keep the medical schools in the black, thus obviating the necessity for federal support.

Contributions, earmarked for any medical school, may be sent to the American Medical Education Foundation at AMA headquarters, 535 North Dearborn Street, Chicago, Illinois.

M.T.(ASCP)

A NEW PROFESSION — Medical Technology—has rather rapidly come into existence.

Prior to 1928, the qualifications of the laboratory technician were vague. That year the American Society of Clinical Pathologists, under the direction of Dr. Kano Ikeda of Saint Paul, set up a national registry of clinical laboratory technicians and established preschool and training standards for students. At first, high school graduates were admitted to the laboratory schools. Later, one year of college and then two years were required. Today most matriculates are college graduates.

Likewise, the American Society of Clinical Pathologists undertook the standardization of the training schools. Later, this was done in co-operation with the Council on Medical Education and Hospitals of the American Medical Association, and in 1935 the Council took over entirely.

The registered technicians organized as the American Society of Clinical Laboratory Technicians at a meeting held in Chicago in June, 1933. The next year the society's first publication, known as *The Bulletin of the American Society of Clinical Laboratory Technicians,* appeared. In 1936 the name was changed to *The American Journal of Medical Technology.*

With the increase in preschool requirements and better technical training, the term technologist was adopted instead of technician. The national society became the American Society of Medical Technologists. The purpose of the society is self betterment and the encouragement of mutual understanding between members and other medical and scientific organizations. Membership is restricted to those registered by the American Society of Clinical Pathologists.

An attempt was made to obtain the exclusive right to the letters M.T. to designate a Medical Technologist registered by the American Society of Clinical Pathologists. That having failed, the designation M.T.(ASCP) was adopted.

The standards of the Registry have been approved by the American Medical Association, the American College of Surgeons and the American Hospital Association. The AMA and the ACS, in their inspection and standardization of hospitals, stress the necessity of having registered (ASCP) laboratory personnel.

The American Society of Medical Technology is composed of numerous state societies. It holds annual meetings which until 1947 were held in conjunction with the annual ASCP meetings. With the increase in membership (about 5,000 in 1951), the Society has met independently since 1947.

Many commercial schools for the training of laboratory technicians have been established throughout the country to meet the growing demand. The graduates of these unrecognized schools are not qualified for registration with the American Society of Clinical Pathologists, nor are they eligible for membership in the American Society of Medical Technology.

The article entitled "Medical Technology" by Sister Alcuin, which appears in this issue, goes further into the distinctive features of M.T.(ASCP), about which we venture to say the average physician is quite ignorant.

The American Society of Clinical Pathologists deserves much credit for having elevated medical technology from its initial state of chaos. The American Society of Medical Technologists is to be congratulated on having established high ideals for its membership and having made a profession of medical technology.

We are indebted to Miss Frieda H. Clausen, M.T.(ASCP) of the Charles T. Miller Hospital Laboratory, Saint Paul, who is chairman of the Public Relations Committee of the American Society of Medical Technologists, for the material used in this editorial.

AS OTHERS SEE US

OFTEN a tourist who sets out to see a foreign country actually sees points of interest the native has never taken time to investigate. How many natives of the Twin Cities have ever visited the local flour mills or breweries? The impressions of an English physician* who spent last summer visiting the medical centers of Canada and the United States make interesting reading and afford food for thought.

The author made prearranged stops of two or three days at the various medical centers throughout the United States and Canada. His remarks were limited to impressions he received of the United States, and having visited our country on previous occasions, he was able to note changes and trends that possibly have escaped our notice.

His discovery of the conveniences and ultimate economy of nylon wear for a summer traveller is an interesting contribution and a recent development.

He discovered that there is more to this country than the eastern seaboard and Chicago. He also found that Chicago is not typically American with its 2 per cent of school children drug addicts, its 12,000 hopeless alcoholics who frequent skid row, its 800 bars which present nightly strip-tease shows and its daily newspaper which "in the art of misrepresenting news makes Pravda look like an inexperienced amateur." Not a pretty picture of Chicago, and he would be the first to admit that he has picked out the worst features of that large metropolis.

He was impressed by the enormous present-day demand for psychiatric treatment which may indicate a "failure of the priest and practitioner to cope with the needs of a sick society." And he mentions the concern of the present-day psychiatrists over the growth of "momism" (dependence on mother) which is so evident in the new generation. "The mistaken application of Freud's teaching to the raising of children has produced many spoiled, unhappy adolescents who are beginning only now to find out that the adult world does not automatically give them everything they want." We wonder whether there is anything distinctly new in this lack of discipline in the bringing up of children.

He realizes that the British newspapers, like other newspapers, report the more squalid things that occur in America, and this gives a false impression of life in America. Such items are considered news.

He feels it unfortunate that politics in America have been so largely in the hands of disreputable people and hopes for a change as America grows up politically. We see some slight indication that the talented youth of our country are going to enter the political arena, an indication of growing up politically. Certainly, there is much evidence of more interest in world affairs as a result of our having been forced as a nation into world leadership.

The public demand for medical research and the amount of money and equipment devoted today to this activity in our country, he found staggering. The average physician is not in a position to see this activity on the part of the many pharmaceutical houses, the numerous universities, the Veterans Administration and the various research centers. The author found the belief in dramatic, even violent, progress to be a part of 20th Century American thinking. Something new, announced in *Time*, sometimes even in advance of a medical journal, is often demanded by the public, even though its value is not yet proven.

Whether right or wrong, he feels that the profession has slipped from the high pedestal on which it stood ten years ago. He thinks the physician of today is considered less altruistic than ten years ago and is perhaps trying to run a closed shop. This impression may well be the result of the united action taken by the profession in opposing regimentation by the government. The accusation of using closed-shop methods is rather farfetched.

The author seems to resent the attack of the AMA on the British National Health Service. He has responded with the retort that without an honest local government we could not succeed with a national health service. We, in turn, wonder whether there is any essential difference between the attitude of the British and American people towards their respective governments.

The author takes a slap at our smugness in thinking that our medicine is the best in the world. He thinks we should send more young doctors over to England, which would correct this impression.

---

*Meikeljohn, A. P.: The American scene. Lancet, 262:45 (Jan. 5) 1952.

While on his visit, he saw no signs that the American public wants a national health service. On the other hand, he sees, as we have seen, a threat to the private practice of medicine in the expensive building program being undertaken by the Veterans Administration. It should be an easy step to include families of veterans among those provided with medical care.

His reaction to the clinicopathological conference which has become so popular in our country is interesting. He feels that these conferences are the highest test of clinical honesty and observes that the professor need not and does not lose the respect of the students if he fails by clinical methods to reach the correct conclusion. The failure often indicates the limitation of clinical methods.

No mention was made of the remarkable change in therapeutics manifest in these United States the past ten years. It is said that 90 per cent of present-day medication was unknown ten years ago. This seems quite likely when we consider the sulfas, antibiotics, anti-histamines, glandular extracts, et cetera. The advance made in thoracic surgery during the past ten years as well as color television and its adaptation to teaching certainly should be mentioned.

Truly, it is a changing medical world.

THE GROWTH OF PREPAID MEDICAL CARE PLANS

(Continued from Page 324)

Blue Shield will be adapted to follow in the footsteps of agreements reached between hospitals and doctors.

It might be of some interest, however, to recite the measure to which Blue Shield Plans are now providing payment for the services of the profession that have been involved in this controversy for several years.

Twenty-eight of the seventy-eight Blue Shield Plans are now offering laboratory services as performed by the pathologist; forty of the seventy-eight Plans are offering diagnostic x-ray benefits as rendered by the radiologist; and fifty-six of the seventy-eight Plans are providing anesthesia benefits as rendered by the medical anesthetist.

Improvement on this rather controversial situation awaits upon the desires of the medical profession and its own established relationships with hospitals, rather than upon Blue Shield.

Although Blue Shield Plans were born, for the most part, in an atmosphere of political expediency and were accepted by some members of the medical profession as the lesser of two evils, in most instances they have found a remarkable degree of acceptance by the American public. From rather humble beginnings a short number of years ago, they have grown to the point where they are serving areas comprising most of these United States and have succeeded in enrolling more than 21,000,000 people. The growth of Blue Shield is proceeding at a rate more rapid today than at any other time in Blue Shield history. No one would dare predict a saturation point, although many of us would hope that Blue Shield would continue to grow until every citizen in the United States has been given an opportunity to subscribe to its benefits.

In spite of the amazing progress that has been made, it would be unwise and even foolish to say anything more than to admit that Blue Shield is still in its infancy. There is much to be learned about what can be done in the direction of applying insurance principles to the practice of medicine, and there is even more to be learned, both by the administrators of Blue Shield Plans and the leaders of organized medicine, in terms of persuading the practitioners of medicine that "what is good for the people is good for the medical profession."

Blue Shield is, truly speaking, an offspring of the medical profession itself. It seeks to serve the interest and the professed need of the public, and at the same time permit the medical profession to preserve its freedom and the intimacy known to be necessary in the relationship between physician and patient.

If Blue Shield is to succeed in accomplishing its avowed function, it will come as a result only of clear-headed management, and the earnest co-operation of the medical profession in the establishment of wise policies.

Medical Economics

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

FARM GROUPS HOLD OPPOSITE HEALTH VIEWS

Surprising as it may seem, two prominent farm groups have recently put forth programs with flagrant contradictions on health insurance in America. The one is a well-known "liberal" farm organization which states its 1952 views on the subject in capital letters: ". . . THERE MUST BE NATIONAL HEALTH INSURANCE." The other is a clear statement of ideas: "We believe that one of the greatest prerogatives of an American citizen is the right to provide for himself and family those services which can best be had by co-operative effort.

"Therefore, we favor the expansion of Voluntary Health Service and unalterably oppose the Government Compulsory Health Program. We want to maintain our freedom to choose our medical and hospital care."

The so-called "liberal" farm group maintains that everyone must be able to afford medical treatment and hospitalization, that these are life-and-death matters and should not depend on the size of a person's bank account. "Anyone needing medical treatment or hospitalization should get it at once without first having to prove he can pay," the program states. Apparently this group does not realize that the medically indigent do have a chance for free medical treatment, for, according to Dr. Frank Dickinson, director of the American Medical Association's Bureau of Medical Economic Research, "the doctors during the depression of the 1930's gave about one-third of their time in 'free services' and about one-sixth at the present time."

Favors Medical School Subsidy

The group also asserts that there is a shortage of doctors: ". . . first, that our nation have ample physicians, dentists, and nurses. But the present system has not been able to supply them. We have never had enough rural doctors. Now the doctor-nurse shortage grows worse."

The organization seems to forget, however, that it is that very system which has increased the life span of the average person twenty years and contributed to the present increased awareness of health matters, thus creating in areas where there is merely a slight maldistribution of doctors, a hue and cry that there are not enough of them.

And so the all-inclusive statement is made: "We advocate *whatever* program can best cure this shortage. Medical schooling and research are already heavily subsidized by government, but medical schools need more government money. We say give it to them." Such a blind and blanket acceptance of *any* possible program certainly would make any thinking agricultural leader hesitate to accept other policies of the group.

This group is no doubt vitally interested in its members' health facilities, but is it not also interested in how those members get those facilities? Do they want to take a chance on getting a program which would bring restrictive government controls and the accompanying mismanagement?

Opposes Prepayment Plans

The group also overlooks the great strides which have already been made by voluntary health insurance in the past years. Apparently they have not noticed that many millions of Americans are now protected from the disastrous costs of unexpected illness through voluntary plans such as Blue Cross and Blue Shield. And these strides are made under the present system which they say has not provided adequate medical care. They would rather have health insurance inspired by politicians than inspired by doctors, for they advocate:

> "Until national health insurance becomes a reality, we urge people to protect themselves with health insur-

ance carried with a co-operative insurance company. . . . We oppose medical prepayment plans inspired by doctors and hospitals and not controlled by the insurance laws that protect policyholders in true insurance companies."

DOCTOR SCORES FEDERAL MEDICAL WASTE

Manifestation of just such control and mismanagement resulting in waste is seen in the recent statement of Dr. Robert Collier Page, chairman of the National Doctors Committee for Improved Federal Medical Services. Dr. Page said: "The Government is by far the largest single employer of physicians and operator of hospitals in the country. But its vast medical plant, spread over thirty-five separate agencies, is devoid of central planning. As a result, U. S. taxpayers are nicked $2 billion a year for a disorganized program that needlessly squanders both money and professional personnel."

Confusion Reigns

After charging that confusion reigns in government medical departments because of lack of central planning, too many needless bulletins on internal procedures and methods which defy intelligent execution, too much control in places and not enough in others, Dr. Page blames much of the Government-medicine inefficiency on "Congressmen who play pork-barrel politics. All too often, the question of where a new Federal hospital should be built is decided by political considerations rather than on the basis of need and accessibility." He cites an example of a hospital built in a small town of 9,184. This hospital has "no medical director, no chief of medical services, and no patients"—although it cost $50,000 a bed to build. And the town is already adequately serviced by a 135-bed general hospital.

Dr. Page also states that Government hospital construction is seldom reconciled with community projects aided by Hill-Burton funds. "Because there is no overall program of hospital construction" the Hill-Burton plan has often "been interfered with by the construction of Federal hospitals" . . . which "offer higher pay and more security for personnel" and "has in some places seriously crippled the staffs of these community hospitals."

EDUCATION FOUNDATION PLANS BUSY YEAR

Dr. Elmer L. Henderson, past president of the American Medical Association, made the principal address at the recent conference of state leaders of the American Medical Education Foundation, and sounded the keynote for the ensuing year: "Though much was done in '51—there's more to do in '52." He stated that the year 1952 will be one filled with many decisions, none of which will be more important than that of giving added financial support to medical schools.

The one-day conference in Chicago was held to stimulate action by the individual states for the current drive which will be conducted from April 1 through June 30.

Policy Change Explained

The Foundation also inaugurated a new fund-distribution policy which was explained at this meeting: "In 1952, gifts which have been designated for a specific medical school will be added to that school's basic grant from earmarked funds. In 1951 all earmarked gifts went to the schools for which they were designated but were included with unearmarked funds in computing the basic grants. Under the new policy if Medical School A's share of the unearmarked funds is $20,000 and earmarked funds totaling $5,000 have been received for Medical School A, the school will receive a total grant of $25,000."

AMA Gives Another Half Million

As it did at the establishment of the Medical Education Foundation, the American Medical Association has given an additional half million dollars to serve as the nucleus for the year's fund. The association is also underwriting expenses of the Foundation so that all philanthropies can be directed to medical schools.

During the first year of the Foundation's operation, more than 1,800 individual physicians contributed to the total of $745,917.84 received by the Foundation. In addition, thirty-three organizations and thirty-three lay persons made contributions. A recent editorial in the *Journal of the American Medical Association* commented: "Although short of the hoped-for goal, these results may be considered reasonably satisfactory for a new undertaking of the magnitude of the Foundation."

Deans Express Appreciation

Formal thanks for funds already allocated were expressed in a resolution from the Association of American Medical Colleges thus: "Resolved, that the deans of the medical schools in assembly for their sixty-second annual meeting unanimously expressed their sincere appreciation and their enthusiastic thanks to the Directors and officers of the American Medical Education Foundation for their substantial support of medical education and for helping to focus national attention on the serious financial predicament of the medical schools."

The AMA editorial also states that the Foundation's activities have been instrumental in creating awareness of the medical schools' needs. It concludes:

> "There is much evidence that the activities of the Foundation are developing a greater awareness and interest in the needs of the medical schools on the part of physicians generally. Many physicians are recognizing for the first time the debt they owe their medical schools while many others see in the Foundation an opportunity for the medical profession to again demonstrate its willingness to aid in the advancement of high standards of medical education. . . .
>
> "The Foundation is thus off to a good start in its second year. All signs point to a successful effort which will constitute a real challenge to industry, business, agriculture and other important groups concerned with medical education to contribute generously to the solution of this important problem."

PRESENT DAY PARALLELED WITH ROMAN DECLINE AND FALL

Most historians agree that the decline and fall of the Roman Empire was due to an overabundance of ignorance, suspicion, envy, discord, selfishness, fear, bitterness and jealousy among the people and the rulers. There was conspicuous absence of science and reason, and a bigotritic centralized government prevailed. The turmoil resulted in the inevitable decline and fall.

A recent editorial in the *Journal of the Oklahoma State Medical Association* draws a similarity in this situation to today's conditions in America, stating that "today in the United States science and reason are being threatened by similar centralization of power at the seat of government."

Power Absolute; Liberty Obsolete

The editorial asserts the belief that too much power in the government is dangerous:

> "When power becomes absolute, liberty will become obsolete and the would-be Augustus Caesar will take over. Medicine looms large in the realm of science and reason, and history shows that the regimentation of the medical profession and the people in need of medical care, has served well the obsessive Caesar, psychology which prepares the way for political coercion, Decline and Fall.
>
> "At least twenty civilizations have succumbed but archeological excavations for the amazement of their successors have no appeal for the American citizenry. Yet the federalization of medicine if it comes, will give the U. S. a front seat on the toboggan that swiftly moves toward the point of no return where oblivion has enveloped successive civilizations in subterranean mold."

THE MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

230 Lowry Medical Arts Building
Saint Paul 2, Minnesota

Julian F. DuBois, M.D., Secretary

MINNESOTA LICENSE OF BREMERTON, WASHINGTON, PHYSICIAN SUSPENDED FOR FIVE YEARS FOR DRUG ADDICTION

In the Matter of the Revocation of the License of Orin P. Thorson, M.D.

The Minnesota State Board of Medical Examiners on February 15, 1952, suspended, for five years, the medical license held by Dr. Orin P. Thorson of Bremerton, Washington. Dr. Thorson was found guilty by the Board of habitual indulgence in the use of dilaudid, codeine and other derivatives of opium, between the 1st day of January, 1951, and the 23rd day of May, 1951. Dr. Thorson appeared in person before the Board and admitted the narcotic charges filed against him.

Dr. Thorson's Minnesota medical license was previously suspended by the Minnesota State Board of Medical Examiners on May 14, 1948, for a period of three years for drug addiction. Subsequently, an investigation by the Federal Bureau of Narcotics disclosed that Dr. Thorson was still addicted to the use of narcotic drugs. Dr. Thorson was born at Madison, Minnesota, September 4, 1900, and received his Doctor of Medicine degree from the University of Minnesota, June 11, 1928. Dr. Thorson practiced, for twelve years, at Northfield, Minnesota, before moving to the State of Washington.

LICENSE OF LAKE CITY PHYSICIAN SUSPENDED FOR THREE YEARS FOR ILLEGAL ISSUANCE OF FRAUDULENT NARCOTIC PRESCRIPTIONS

In the Matter of the Revocation of the License of Donald Laing Peterson, M.D.

On February 15, 1952, the Minnesota State Board of Medical Examiners suspended for three years, the medical license held by Dr. Donald Laing Peterson, Lake City, Minnesota. Dr. Peterson was found guilty by the Board of illegally issuing not less than 14 prescriptions calling for a derivative of opium, between the 1st day of February, 1951, and the 30th day of June, 1951. At that time Dr. Peterson did not have a special tax stamp required under the laws of the United States. Dr. Peterson admitted affixing the names of two Minnesota physicians, without their knowledge or authorization, to the prescriptions. The prescriptions were filled in drug stores at Redwood Falls, Mankato, Owatonna, St. James, Fairmont, Willmar, Minnesota, and Fargo, North Dakota. Dr. Peterson admitted that he diverted the morphine obtained on the various prescriptions to his own use at a time when he had no bona fide medicinal use for the morphine.

Dr. Peterson's medical license was previously suspended by the Minnesota State Board of Medical Examiners on May 12, 1944, following Dr. Peterson's plea of guilty in the United States District Court at Minneapolis, on March 8, 1944, to an indictment charging him with two violations of the Harrison Narcotic Act.

At that time Dr. Peterson was ordered by Judge Gunnar H. Nordbye to place himself in the United States Public Health Service Hospital at Lexington, Kentucky, for treatment for drug addiction. Because of Dr. Peterson's previous difficulty with narcotic drugs, he was not permitted to prescribe or dispense narcotic drugs in his practice at Lake City. Dr. Peterson was born at Casselton, North Dakota, November 7, 1908, and received his Doctor of Medicine Degree from the University of Minnesota, June 19, 1933.

MINNEAPOLIS REAL ESTATE MAN SENTENCED FOR CRIMINAL ABORTION

Re State of Minnesota vs. Adolph Charles Chamberlain.

On March 3, 1952, Adolph Charles Chamberlain, forty years of age, 4052 Vernon Avenue, St. Louis Park, was sentenced by the Hon. Rolf Fosseen, Judge of the District Court of Hennepin County, to a term of not to exceed eight years in the State Prison at Stillwater, Minnesota. However, the execution of the sentence was stayed and the defendant placed on probation for five years. As a condition of probation, Chamberlain must first serve one year in the Minneapolis Workhouse. In specifying other conditions of probation, Judge Fosseen ordered the defendant to turn over to the Probation Department, all medical instruments of every type in his possession. In addition to this, Chamberlain was ordered to delete his name from the Minneapolis Telephone Directory to aid in breaking the contact between himself and any prospective patients desiring abortions. The defendant Chamberlain had entered a plea of guilty on January 25, 1952, to an information charging him with the crime of abortion. The defendant also admitted a prior felony conviction in October, 1937, for using an automobile without the permission of the owner.

Chamberlain was arrested by Minneapolis police officers on January 21, 1952, following the hospitalization of a twenty-year-old Minneapolis divorcee who was suffering from the after effects of a criminal abortion. An investigation revealed that the defendant Chamberlain, who stated he was associated with a Minneapolis real estate concern, had aborted her by means of a catheter on January 12, 1952. The abortion, for which Chamberlain received the patient's promissory note for $150, was done in the evening at the defendant's real estate office. Chamberlain admitted that he impersonated a licensed Minnesota physician at a Minneapolis medical supply company in order to obtain instruments which he later used in doing this abortion.

When Chamberlain claimed in Court that this was the only abortion he had ever committed, Judge Fosseen indicated to the defendant that he did not believe him in this regard. The defendant also stated to the Court that he learned the technique of doing an abortion merely from a conversation with a customer to whom he had sold a house. Chamberlain holds no license to practice any form of healing in the State of Minnesota.

THE DOCTOR'S RESPONSIBILITY TO HIS PATIENT

(Continued from Page 317)

advised as to her condition. Frequently patients ask me, "Do you write my doctor?" When I assure them that I do so and add that "I had a letter from him and he is very pleased that you are progressing satisfactorily," the patient is very appreciative. After all, he still is the family doctor, in whom the patient has unlimited confidence due to his many years of guidance and medical care. There are many other important factors that can be emphasized on this vital subject.

These brief remarks, based on a consultation practice of forty-four years, are simply made, because all of us realize the importance of a close physician-patient relationship, the desire to ease our patients' suffering, both physically and mentally, and to have our patients retain that high degree of confidence without which no physician, however brilliant, is successful.

Our responsibility extends further than to the individual patient. In these days of turmoil it is our duty to be active in our community life, to enlighten the public by addresses sponsored by our county and state societies, not only on scientific subjects but also on other aspects of medical problems.

The danger of socialized medicine is ever present. Although Congress has refused four times to pass the Wagner-Murray-Dingell Bill in its various forms, other schemes are constantly developing. Ewing's proposal to provide hospital and medical care to every person over sixty-five years of age who comes under the Social Security Act, and their dependents, estimated at 143 million, the attempt to have all school children, regardless of financial circumstances, receive free medical examinations, and the ever-increasing tendency for nonservice-connected veterans to obtain free hospital and medical care, are simply entering wedges on whose foundation socialized medicine will develop. With the universal military training in effect, all of us will be war veterans of some sort in the not too distant future. In order to keep our precious American heritage of the private practice of medicine, we must be on the alert, individually contact our representatives in Congress and, collectively, one and all support the American Medical Association, both actively and financially. But for *their* activities at the grass root levels, the Lord only knows where we would be today. Let us not neglect this important duty. Our patient-physician relationship demands it.

Minnesota Academy of Medicine

Meeting of October 10, 1951

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, October 10, 1951. Dinner was served at 7 o'clock and the meeting was called to order at 8:15 p.m. by the President, Dr. W. H. Hengstler.

There were fifty members and four guests present.

Minutes of the May meeting were read and approved.

The scientific program followed.

Dr. Donald Hastings, of the University of Minnesota, read his thesis on "Psychiatry in Medical Education."

Dr. Wesley W. Spink, of the University of Minnesota, gave a talk and showed colored lantern slides of his summer trip to Europe, particularly on Medical Observations in Yugoslavia.

The meeting was adjourned.

Wallace P. Ritchie, M.D., *Secretary*

Meeting of November 14, 1951

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, November 14, 1951. Dinner was served at 7 o'clock and the meeting was called to order at 8:15 p.m. by the President, Dr. W. H. Hengstler.

There were forty-two members and four guests present.

Minutes of the October meeting were read and approved.

The President appointed Dr. Charles Mayo to prepare a Memorial for Dr. A. W. Adson, and Dr. O. S. Wyatt to prepare a Memorial for Dr. Frank J. Corbett, members who had died recently, and report at a later meeting.

The scientific program followed.

Dr. Edmund Flink, of the University of Minnesota Medical School, by invitation, gave a paper on "Bilateral Adrenalectomy for Hypertension."

The meeting was adjourned.

Wallace P. Ritchie, M.D., *Secretary*

Meeting of December 12, 1951

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, December 12, 1951. Dinner was served at 7 o'clock and the meeting was called to order at 8 p.m. by the President, Dr. William H. Hengstler.

There were forty-nine members and one guest present.

Minutes of the November meeting were read and approved.

Dr. O. S. Wyatt read the following Memorial to Dr. Frank J. Corbett.

JAMES FRANK CORBETT

1872 - 1951

Dr. James Frank Corbett was born February 16, 1872; he died on November 6, 1951, at the age of seventy-nine. He received his medical degree from the University of Minnesota in 1896. In 1896-97, he served an internship at the Minneapolis General Hospital. He did graduate work at the University of Michigan, University of Chicago, and the Rockefeller Foundation.

In 1898, he was City Bacteriologist in Minneapolis.

In 1907, he read his Inaugural Thesis before this Academy entitled "Gastric Ulcer with Especial Reference to Malignant Change." It was also in this year that he was appointed Assistant Professor of Surgical Pathology at the University. Between the years 1910 and 1920, he read several papers before the Academy, some of which were in conjunction with Dr. James E. Moore.

In the year 1911, he was appointed Associate Professor of Experimental Surgery. He resigned this position in January 1913, and, under the reorganization, was reappointed in August 1913. He served in World War I from 1916 to 1919, and during that time he was Chief of Surgery at General Hospital in Cape May and Chief of Surgery at Walter Reed Hospital. In 1919, he was appointed Associate Professor of Surgery at the University.

In 1920, he served as President of the Hennepin County Medical Society and in 1923 was President of the Minnesota State Medical Association.

He served as Chief of Surgery at the Minneapolis General Hospital from 1921 to 1925. He was appointed Clinical Professor of Surgery in 1937, and in 1940 he became Emeritus Professor of Surgery at the University.

Dr. Corbett did considerable writing in his younger years; prior to 1928 he published about forty medical articles.

In 1942, he was made an Honorary Member of this Academy.

He was a Fellow of the American College of Surgeons, a member of the American Board of Surgery, the Minnesota Academy of Medicine, the Western Surgical Society, the American Medical Association, and the

◆ Reports and Announcements ◆

INTERNATIONAL COLLEGE OF SURGEONS

A central states regional meeting of the United States Chapter of the International College of Surgeons will be held in Kansas City, Missouri, April 28 and 29, with headquarters at the President Hotel. Members of the surgical profession at large are invited to attend. The program will include general scientific sessions each morning from 9:00 to 12:00 and each afternoon from 2:00 to 5:00; luncheons followed by panel discussions each day; a social hour and dinner on the first evening with Dr. David L. MacFarlane, President of Kansas State Teachers College, as the speaker; and a buffet dinner on the second evening followed by panel discussion of a "Mystery Case," which will be a joint session with the Jackson County Medical Society.

CONFERENCE ON AGING

"Housing the Aging" is the topic for the University of Michigan Fifth Annual Conference on Aging to be held in Ann Arbor, Michigan, July 24 to 26. The three-day conference will consider the housing needs of healthy, chronically ill, confused, and disabled older people living in urban and rural areas.

The conference is directed to national, state, and local planners; physicians, nurses, and public health workers; industrial retirement counselors; welfare and social work personnel; architects, builders, realtors; safety and sanitary engineers; public and private investment and financing agencies; directors of old age homes, nursing homes, hospitals, and housing projects; and to older people themselves who are interested in contributing to the solution of the housing problem of the aging.

The conference is under the co-sponsorship of the Institute for Human Adjustment, Schools of Architecture, Business Administration, Social Work, Public Health, and the Medical School, Extension Service and Summer Session of the University of Michigan; the Michigan State Medical Society; the Committee on Aging and Geriatrics of the Federal Security Agency, Washington, D. C., and the Housing and Home Finance Agency, Washington, D. C.

Conference registration materials may be obtained by writing to Dr. Wilma Donahue, Institute for Human Adjustment, Room 1510, Rackham Building, Ann Arbor, Michigan.

MICHAEL REESE HOSPITAL POSTGRADUATE SCHOOL

The Michael Reese Hospital Postgraduate School, Chicago, is offering the following courses during April and May:

A two-week course in "Diseases of the Endocrines—Physiology and Diagnostic Methods." This full-time, intensive course will meet from April 28 to May 9 and will be under the direction of Dr. Rachmiel Levine, director, Department of Metabolic and Endocrine Research. Basic principles will be presented with a review of recent advances in the field. The course is designed for clinical application.

A two-week course in "Recent Advances in Internal Medicine," from May 12 to 24. This full-time intensive course encompasses a systematic review of recent advances in the various branches of internal medicine. The clinical and didactic material will be presented by members of the Department of Internal Medicine, other clinical departments and the Division of Laboratories and Research.

A one-week course in "Recent Advances in Pediatrics—Diagnostic and Therapeutic Measures," from May 26 to 31. Recent advances in pediatrics, including the presentation of clinical as well as didactic material. For the pediatrician and other physicians who limit their practice largely to children. The course will be presented by the Department of Pediatrics and co-operating departments.

Further information about any of these courses can be obtained by writing to Dr. Samuel Soskin, Dean, 29th Street and Ellis Avenue, Chicago 16, Illinois.

ANESTHESIOLOGY SYMPOSIUM

The University of Pittsburgh School of Medicine, Department of Surgery, Section of Anesthesiology announces a postgraduate symposium on the basic sciences related to anesthesiology, to be held at Pittsburgh June 2 to 6 in co-operation with the Department of Anesthesiology of the St. Francis, Allegheny General, and Mercy Hospitals. The course will be limited to fifty participants. Registration fee is $25.

Registration and full particulars can be obtained from the Chairman of the Committee on Graduate Medical Education, University of Pittsburgh School of Medicine, 3941 O'Hara Street, Pittsburgh 13, Pennsylvania.

MINNESOTA ACADEMY OF GENERAL PRACTICE

The Hennepin County Academy of General Practice will sponsor the dinner and program of the Minnesota Academy of General Practice, which will be held in the Ballroom of the Radisson Hotel, Minneapolis, the evening of May 26, 1952. A social hour at 5:00 p.m. will precede the dinner scheduled for 6:00 p.m.

Speakers for the event will be:

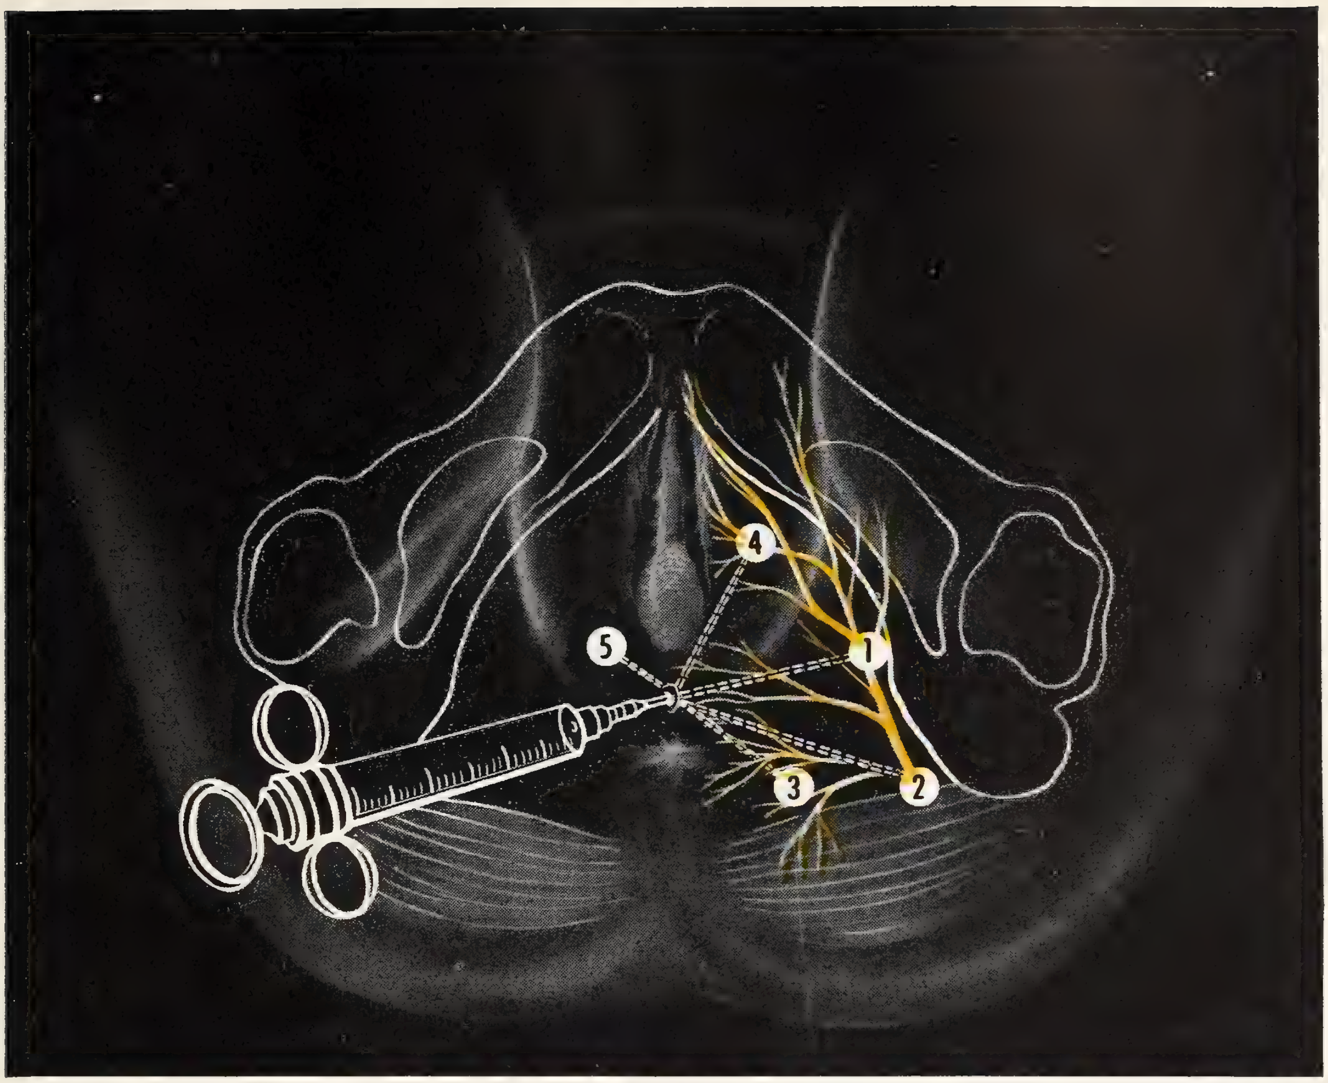
R. B. Robbins, M.D., Camden, Arkansas, Past President of the American Academy of General Practice
"Medicine in This Changing World"

Edward H. Rynearson, M.D., The Mayo Clinic, Rochester, Minnesota
"Is Obesity an Endocrine Problem?"

MINNESOTA PATHOLOGICAL SOCIETY

Dr. C. Keith Simpson, Reader in Forensic Medicine, University of London, and Supervisor of Medico Legal Post-Mortems at Guy Hospital, will give a special lecture

(Continued on Page 360)



Sites for injection of local anesthesia in obstetrics. Sites 1 to 4 should be similarly injected on the contralateral side. Site 5 is for episiotomy. Adapted from Johnson, O. J.: Nerve Block in Painless Childbirth, J.A.M.A. *145*:401 (Feb. 10) 1951.

Pudendal Block in Obstetrics Simplified with **ALIDASE**

Using a local anesthetic with hyaluronidase, Heins[1] reports: "Complete perineal anesthesia is practically instantaneous. . . . The technique of pudendal block is greatly simplified. The operator does not have to inject the nerve per se, but infiltration in the vicinity of the nerve will accomplish an effective block."

Baum[2] states: "The use of hyaluronidase is found to be a safe and simple method for increasing the efficiency of pudendal block in obstetrics and for overcoming many of the objections to this type of obstetrical anesthetic."

ALIDASE® —highly purified, well tolerated brand of hyaluronidase—definitely shortens the period between completion of the block and establishment of operating analgesia. Swelling, induration and discomfort are almost negligible with Alidase.

[1] Heins, H. C.: Pudendal Block with Hyaluronidase, J. South Carolina M. A. *46*:309 (Oct.) 1950.

Therapy for Vascular Headache to Reverse the Physiologic Disturbance

Headache, a problem encountered in all kinds of medical practice, may occur in association with any of a variety of disorders, some organic, other purely functional.

Among the several types, functional headaches present the greatest problem because of their obscure etiology and recurrent nature.

Among these are:

- Migraine (both classical and variant forms)
- Tension headache
- Psychogenic headache
- Histaminic cephalgia

Wolff and his co-workers established that the pain of these headches is due to disturbance of the tonus of cranial blood vessels — hence the term *vascular headaches.*

The craniovascular changes associated with the several phases of the typical migraine attack are:

Vasoconstriction — to which the visual prodromata are attributable. It is possible to abort the attack during this phase in all but a few cases. (See treatment below.)

Vasodilatation — as the vessels lose their tone, exaggerated pulsations set in, resulting in the throbbing pain which characterizes vascular headache. Treatment for the attack is still effective during this phase. (See below.)

Vessel Edema — if the vasodilation continues for too long, vessel walls become edematous; this changes the character of the pain to a steady, intense aching. The attack can now no longer be checked, even with maximum dosage of specific drugs. *Moreover, sustained headache often induces reflex neck muscle tension, a source of residual pain.*

Therapy: 1. Reduce the frequency of attacks — psychotherapy and regulation of living habits to avoid fatigue and nervous tension.

2. Relieve the acute attack — of the numerous drugs which have been tried, ergotamine and its derivative preparations have proved most effective. The newest product is oral tablets of Cafergot®, N. N. R. (ergotamine with caffeine 'Sandoz'). When dosage is adjusted to the needs of the individual, Cafergot will give good relief in 85% of cases. It enables a greater number of patients to benefit from early administration since the oral route simplifies treatment as compared to parenteral therapy.

The dosage procedure is:

1. Take 2 tablets at first sign of the attack.
2. If attack continues, take one additional tablet every ½ hour until attack is terminated *(max. 6 tabs. per attack).*

Many migraine patients delay taking medication until the attack is at its height. Explicit dosage instructions may be forgotten unless the patient comes to realize their importance. Therefore, to encourage adherence to correct procedure, we have prepared pads outlining detailed dosage instructions. Supplies of these INSTRUCTION SLIPS will gladly be sent upon request.

Woman's Auxiliary

PRESIDENT ANNOUNCES ANNUAL MEETING

Mrs. F. P. Moersch

Plans for the 1952 annual meeting of the Woman's Auxiliary to the Minnesota State Medical Association have been completed and offer an interesting and stimulating slate of events for doctors' wives from throughout the state.

This year's meeting will be held May 26, 27 and 28 in Minneapolis, with the Hotel Radisson as headquarters. Registration opens at 8:00 a.m. each morning, and there will be advanced registration beginning late Sunday, May 25.

The Executive Board meeting will begin at 11:00 a.m., Monday, May 26, at the College Women's Club, with a luncheon following at 1:00 p.m. At 3:30 p.m., Monday, the annual tea honoring state officers will take place at the Swedish Art Institute.

The annual meeting will be held at the Woman's Club of Minneapolis beginning at 10:00 a.m. on Tuesday, May 27, with the annual luncheon following at 1:00 p.m. On Wednesday morning, May 28, there will be the annual breakfast. Annual meeting programs will be mailed to members just before the meeting.

Another interesting feature of this year's meeting will be guided tours through General Mills' kitchen and several Minneapolis radio stations.

Your president urges you to take this opportunity to become better acquainted with your state auxiliary organization. A warm, friendly welcome will await you in Minneapolis. Be sure to attend.

MEDICAL TECHNOLOGY

(Continued from Page 335)

is known as the Minnesota Society of Medical Technologists and holds a charter from the ASMT. The MSMT is incorporated in Minnesota. Within the state society are district societies of which there are five geographically but four functionally. The largest and oldest is the Twin City organization. The second is the Arrowhead. The other two include the area in which the Mayo Clinic is located, and the area embracing an angular territory with Bemidji and St. Cloud as the largest centers.

The intended purpose of this article is to solicit the aid of the medical profession in solving the problems confronted by registered medical technologists (ASCP). Knowledge is the first attribute and in the wake of this all else adjusts itself.

In Memoriam

WERNER HEMSTEAD

Dr. Werner Hemstead, formerly mayor and a prominent resident of Brainerd, Minnesota, died March 12, 1952, in Rochester. He was ninety-one years of age.

Dr. Hemstead was born April 19, 1860, in Sherills Mound, Iowa. He came to Brainerd in 1882 after taking his medical degree and practicing six months in Nebraska. He served six years as assistant surgeon at the Northern Pacific Hospital which was located at Brainerd at that time.

Dr. Hemstead was active in civic affairs, having served as mayor, city council member, member of the board of education, president of the Crow Wing County Agricultural Society and as county physician. He also served as representative from Crow Wing County in the State Legislature in 1891 and 1892.

On leaving Brainerd, he served as resident physician at the St. Cloud reformatory for a number of years and later as resident physician at the Fergus Falls state mental hospital. In recent years, he resided with his son in Minneapolis.

ROBERT HODAPP

Dr. Robert Hodapp, a practicing physician at Willmar for more than thirty years, died March 17, 1952, at the age of sixty from a heart attack.

He was a past commander of the Willmar American Legion post and had served as president of the Chamber of Commerce. He was also president of the Willmar school board, of which he had been a member since 1941.

HAROLD JOSEPH PRENDERGAST

Dr. Harold Joseph Prendergast, a member of a pioneer Saint Paul family, died quietly at his home at Turtle Lake, near Saint Paul, February 22, 1952.

Dr. Prendergast was born July 17, 1897, in Saint Paul, the son of James J. Prendergast and Anna Katherine Mitsch Prendergast. He received his primary education in Saint Paul schools. He graduated from St. Thomas Military Academy in 1915. He entered the University of Minnesota as a pre-medical student in 1915 and received the degree of Bachelor of Science in 1920. His course was interrupted temporarily in 1918 while he served in the United States Army in World War I. He received the degree of Bachelor of Medicine in 1922 and was licensed to practice in the State of Minnesota at that time. He served an eighteen-month internship at Ancker Hospital in Saint Paul, completing it in 1923, at which time he received the degree of Doctor of Medicine from the University of Minnesota.

He married Catherine Belle Leahy, March 1, 1924, and was the father of two children: a son, Harold James, and a daughter, Mary, now Mrs. Louis Pabst.

Dr. Prendergast practiced in Brainerd, Minnesota, from 1923 to 1925, at which time he returned to Saint Paul where he practiced medicine and surgery until he retired, May 31, 1950. He was Chief Civil Service Medical

Examiner for the City of Saint Paul, and a member of the Staffs of St. Joseph, Ancker and Children's Hospitals. He was a member of the Ramsey County Medical Society, Minnesota State Medical Association, American Medical Association, Medical Club of Saint Paul, Catholic Order of Foresters, and American Legion Post No. 8.

Dr. Prendergast was an exemplary Catholic, and was beloved by his patients, associates and a host of friends. He never spared himself in attending to his professional duties. His great devotion to young people was one of his outstanding characteristics which made his home a rendezvous for his children's friends. His passing will be mourned sincerely by his family, friends and medical contemporaries.

John M. Culligan, M.D.

WILLIAM L. PALMER

Dr. William L. Palmer, a former resident of Albert Lea, Minnesota, died March 8, 1952, at the Naeve hospital in Albert Lea.

He was born in Freeborn County, September 22, 1867, and spent his early boyhood at Glenville. He obtained his M.D. degree at Rush Medical College in 1896 and practiced at Glenville for ten years before moving to Albert Lea.

Dr. Palmer was married June 17, 1895, to Ida May Trow. With his son, Dr. C. Foster Palmer, and others, he established a surgical and medical clinic in Albert Lea in 1940. He was a member of the Freeborn County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Palmer was an example of what determination and ability can accomplish. At the age of five he lost his father, when fifteen he lost an older brother, and from then on became the chief support of his mother. He taught school and engaged in the milling business in Wisconsin in order to provide funds for the study of medicine. He attained his ambition to render medical service to his fellow men.

NORMAN MARSHALL SMITH

Dr. Norman M. Smith of Minneapolis died February 22, 1952, at the age of seventy-six.

Dr. Smith was born in Monticello, Iowa, September 22, 1875. He received his M.D. degree at Hahnemann Medical College, Chicago, in 1902. He took postgraduate work at the Lying-In Hospital, New York, in 1926.

He was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association, the Minnesota Pathological Society, the National Gastro Enterological Association, the Mississippi Valley Medical Association and the McDonough Society for Medical Research.

Dr. Smith had been medical director for the Minneapolis Aquatennial. He was a member of Plymouth Congregational Church and of the Masonic Lodge and the Minnekahda Club.

He is survived by his wife; a daughter, Mrs. Eleanor Meagher, Minneapolis; a brother, and two sisters.

One supply source for physicians, hospitals, laboratories

In establishing this new store, the A. S. Aloe Company was governed solely by one aim: that of bringing faster, better service to physicians, hospitals and laboratories in this area. Here you will find functional displays designed to eliminate confusion in making your selections. Visit us to see new equipment; call us for prompt emergency service. Free parking is provided adjacent to building. Telephone: LIncoln 7601.

a. s. aloe company OF MINNESOTA • 927 Portland Ave. • Minneapolis 4, Minn.

◆ Of General Interest ◆

Dr. E. M. Hammes, Sr., of Saint Paul, chairman of the Medical Testimony Committee of the Minnesota State Medical Association, gave an address in St. Louis, Missouri, on March 29, on the subjects "The Medical Expert Witness" and "The Minnesota Plan for the Control of Medical Testimony." The address was given upon invitation of the Missouri Society of Pathologists in co-operation with the Missouri State Medical Association and the legal profession.

* * *

Dr. Thomas J. Kenyon, formerly associated with Dr. John Lepak, has opened a new office for the practice of internal medicine at 223 Lowry Medical Arts Building, Saint Paul.

* * *

Nine phases of the treatment of cerebral palsy were discussed at the third symposium conducted by the Research Council of **United Cerebral Palsy** on March 28 at Cleveland. General theme of the symposium was "Appraisal of Current Methods of Treatment of Cerebral Palsy."

Among the physicians who appeared on the program of the symposium was **Dr. John F. Pohl,** Minneapolis, who spoke on "Function of Ancillary Services in the Treatment of Cerebral Palsy." Dr. Pohl is the author of *Cerebral Palsy*, a textbook on the diagnosis and treatment of the condition.

* * *

Dr. F. L. Bregel resumed his medical practice at St. James late in February after having served as a staff physician at the St. Peter State Hospital for the preceding six months.

* * *

Dr. William H. Card, Minneapolis, has moved into new quarters at 1641 Medical Arts Building. His practice is limited to urology.

* * *

Among Minnesota physicians attending the annual clinical conference of the Chicago Medical Society during the first week of March was **Dr. Walter E. Hinz** of Willmar.

* * *

Dr. O. L. N. Nelson, Minneapolis, spoke on the "Menace of the Medicine Chest" at a meeting of the Commonwealth Club in Minneapolis on March 7.

* * *

On March 2, **Dr. B. T. Bottolfson,** Moorhead, celebrated the thirty-fifth anniversary of his start in the practice of medicine. A native of Moorhead, Dr. Bottolfson became a graduate of the University of Minnesota Medical School in 1916. After interning at Minneapolis General Hospital, he began practice at Kindred, North Dakota, on March 2, 1917. He returned to Moorhead following a period of service in the Army during World War I and has since practiced there. He specializes in ophthalmology and otolaryngology.

* * *

Dr. L. M. Evans and **Dr. R. J. Cesnik** have moved into new offices at Sauk Rapids. Their new location provides considerably more office space than their former quarters.

* * *

After attending a graduate medical assembly in New Orleans early in March, **Dr. and Mrs. Hobert J. Setzer,** Saint Paul, were among a group who flew to Mexico for a tour of the country and its medical clinics. They returned by plane to the United States on March 29.

* * *

Dr. C. M. Adkins. Thief River Falls, one of the oldest active practicing physicians in Minnesota, celebrated his eightieth birthday anniversary on February 23. Dr. Adkins has practiced at Thief River Falls and nearby Grygla since 1912. He still maintains regular office hours at Thief River Falls and drives to Grygla for consultations one day each week.

* * *

Three fellows in the Mayo Foundation, studying at Rochester, received master's degrees at commencement exercises at the University of Minnesota on March 20. **Dr. William J. Block, Jr.,** and **Dr. Hugh H. Hanson** received M.S. degrees in medicine, while **Dr. K. J. Monsour** received a M.S. degree in psychiatry.

* * *

During the first half of March **Dr. John Eiler,** Park Rapids, first spent a week in Chicago, taking a course in surgery at the Cook County Hospital, followed by a week at New Orleans, where he attended a postgraduate medical assembly.

* * *

Dr. C. S. Youngstrom, formerly of Vinton, Iowa, has joined the staff of the East Range Clinics, Eveleth. A graduate of the University of Nebraska, he specializes in urology.

* * *

Dr. Gordon R. Kamman, Saint Paul, spoke on "Psychotherapy in Psychosomatic Medicine" at a meeting of the Park Region Medical Society at Fergus Falls on February 29.

* * *

It was announced on March 14 that **Dr. E. W. Lippmann,** Hutchinson, had resigned as a member of the city recreation board. He told the city council that he was forced to relinquish the position because of the press of professional affairs.

* * *

Dr. Robert L. Parker, Rochester, was a speaker at the Saint Paul Medical Forum on March 5. His topic was "Cardiac Disease of Unusual Etiology."

Dr. C. A. Anderson, Hector, attended the General Practitioners National Convention at Atlantic City, New Jersey, during March. He was away from Hector for about three weeks, and during his absence all emergency cases in his practice were taken care of by Dr. H. P. Hinderaker of Bird Island.

* * *

Dr. James Troghele, formerly of Corte Madera, California, has joined the medical staff of the Hastings State Hospital.

* * *

Dr. Leonard F. Peltier, University of Minnesota Medical School, is one of twenty-one young scientists recently named as the fifth group of Scholars in Medical Science by the John and Mary R. Markle Foundation. With the appointment goes a grant of $30,000 for support of each scholar and his research —$6,000 annually for five years, paid directly to his medical school. Dr. Peltier is a clinical instructor and senior resident at the University of Minnesota Medical School, and his special fields of interest are orthopedic surgery and surgical pathology.

* * *

Dr. James T. Priestley, Rochester, was elected president of the Central Surgical Association at the ninth annual assembly of the association at Toronto, Canada, on March 8. He had served as secretary of the organization for the past three years.

* * *

Dr. L. H. Flancher, superintendent of Sunnyrest Sanatorium, Crookston, was the principal speaker at a meeting of the Crookston Exchange Club on March 4. He urged all residents of Crookston to participate in the Polk County chest x-ray survey, conducted during February and March.

* * *

Dr. John Stam, Worthington, attended the semiannual meeting of the Northwest Pediatrics Association at Saint Paul on March 7.

* * *

Two new physicians have joined the staff of the Bratrud Clinic at Thief River Falls. They are **Dr. Forrest A. Rowell,** formerly of Hastings-on-Hudson, New York, and **Dr. Harold D. Kletschka,** formerly of Brainerd.

Dr. Rowell, a graduate of Tufts College Medical School, after completing his internship served in the Army from 1940 to 1945. Following the war he took postgraduate work in obstetrics before beginning practice at Hastings-on-Hudson and Yonkers, New York, where he was on the obstetrical staff of Yonkers General Hospital and St. John's Hospital.

Dr. Kletschka, a graduate of the University of Minnesota Medical School, served his internship and took a year of surgical training at Kings County Hospital, New York. He then spent two years studying general and thoracic surgery at the University of Michigan Hospital, Ann Arbor.

* * *

At a meeting of the Rochester Chapter of the Izaak Walton League on March 11, **Dr. M. C. Pet-**

ersen, of the Rochester State Hospital, described the progress of the Minnesota mental health program during the past 100 years.

* * *

"Your Child and His Mental Health" was the topic discussed by a panel at a Parent-Teacher Association meeting in Winona on March 17. Among the participants in the panel was **Dr. C. W. Rogers,** Winona.

* * *

Among those appearing on the program of an Olmsted County Farm and Home Safety meeting at Rochester on March 11 was **Dr. H. Herman Young,** Rochester, who gave an illustrated talk on farm and home accidents and their prevention.

* * *

The late **Dr. M. W. Kemp,** formerly of Moose Lake, is to be honored by the Cragmont Hospital at North Madison, Indiana, where he was superintendent for four years. A new employes' building there will be named in his honor, and an oil portrait of him will be hung in the lobby. Dr. Kemp was the first superintendent of the Moose Lake State Hospital and served there from 1938 to 1946.

* * *

Dr. George R. Smith, Hutchinson, spoke on cardiovascular diseases at a meeting of the Kiwanis Club in Hutchinson on February 19.

* * *

A total of 1,507 persons enrolled in the Becker County Flood Bank during its initial membership campaign in February, it has been announced by **Dr. C. W. Moberg,** Detroit Lakes, chairman of the campaign. The blood bank is a type of insurance program that costs nothing to join. By promising to donate a pint of his blood when called, a member secures protection for himself and any member of his family in case of critical illness. It is believed that the Becker County membership is large enough so that no member will be called upon to donate blood more often than once every three years.

* * *

It was announced on March 12 that applications would again be accepted from men who wished to be examined for evidence of cancer at the University of Minnesota Cancer Detection Center. **Dr. Thomas B. Hubbard,** acting director of the center, said that the list of men applicants had been exhausted.

Applicants must be Minnesota residents over forty-five years of age and apparently in good health with no obvious symptoms of cancer. Applicants must write to the center for appointments; none will be made by telephone. An examination fee of $25 is charged those who can afford to pay.

* * *

Among the speakers at a meeting of the Parent-Teacher Association at Lincoln School in Austin on March 11 was **Dr. Paul C. Leck,** Austin, who discussed the month's PTA theme: "We Will Help You To Grow in Health."

* * *

Dr. William Chalgren, Mankato, was the principal speaker at a meeting of the YWCA Young Mothers Club in Mankato on March 13. He spoke on the topic, "In Defense of Mothers."

A mental health workshop for nurses was conducted at St. Gabriel's Hospital, Little Falls, on March 20 and 21. Among the faculty members for the course, who presented discussions of various problems in mental health, was **Dr. Alexander Watson,** Little Falls, health officer of District 8, Minnesota Department of Health.

* * *

As an inducement to persuade additional physicians to move to Mabel, a local druggist has announced plans for the construction of a clinic building there. It is expected that construction work on the one-story structure, with facilities for two physicians, will start this spring. The clinic will be equipped through donations from local groups, with ownership of the equipment retained by the Mabel Hospital Association.

Physicians interested in moving to Mabel would be able to rent the building's office space and have use of the equipment. At the present, Mabel has only one physician, **Dr. Justin Lannin,** who has practiced there for thirty-eight years.

* * *

A Mayo Memorial, in honor of the famous surgeons and their father, is being constructed at Rochester near the Mayo Civic Auditorium. The outdoor memorial, which will include statues of **Dr. Charles H. Mayo, Dr. William J. Mayo** and **Dr. W. W. Mayo,** is intended to serve as a perpetual shrine to the memory of the three great physicians. Plans call for dedication of the memorial on September 27.

* * *

"Emotions of Children" was the title of a talk given by **Dr. David A. Sher,** Virginia, at a Parent-Teacher Association meeting at Eveleth on February 21.

* * *

Dr. and Mrs. C. L. Sheedy, Austin, sailed from New York on March 14 for a tour of Europe. Plans call for their return to the United States early in May.

* * *

Dr. Ali Gharib, of Iran, a Mayo Foundation fellow in anesthesiology, was the principal speaker at a meeting at the Recent Grads Division of the America Association of University Women in Rochester on March 3. He described the living conditions and customs of Iran. Dr. Gharib expects to return to Iran after he completes his three-year fellowship with the Mayo Foundation.

HOSPITAL NEWS

The new **Winnebago Hospital** is expected to open its doors sometime during April, it was announced late in February. All of the nine patient-rooms in the eighteen-bed hospital have been completely furnished as memorials or gifts from families or organizations.

* * *

Abbott Hospital, Minneapolis, observed its fiftieth anniversary on March 5. Open house was held at the hospital on the afternoon of that day.

When the hospital was founded in 1902 by Dr. Amos W. Abbott, it was housed in a three-story apartment building and had facilities for fifteen patients. Today Abbott Hospital has 152 beds and 24 bassinets.

Dr. Abbott, who first began practice in Minneapolis in 1877, died in 1927 after having contributed much to advance medical facilities in the city.

* * *

Financial operating problems of the **Winona General Hospital** were discussed at a meeting of the Winona Exchange Club on March 11. Principal speaker at the meeting was Mrs. Sara Goyanes, member of the hospital's Service and Information Committee. Also participating was Dr. Paul Heise, pathologist and chief of the medical staff of the hospital.

Among points emphasized in the discussion were (1) the average daily house count at the hospital has dropped from 81 in 1946 to 55 in 1951; (2) the average length of stay per patient has dropped from 12 days in 1946 to 7.3 days in 1951; (3) costs have risen sharply. It was pointed out that "if everybody in the hospital last year had stayed there one more day, the hospital would have been in the black." As it is, it was stated, the hospital is losing $2.30 for every adult patient day.

EXCELLENT CARE TO CONVALESCENT AND CHRONIC PATIENTS

Rates Reasonable. Patients under the care of their own physicians, who direct the treatment.

5511 Lyndale Ave. So. LO. 0773 Minneapolis, Minn.

Dedication ceremonies for the new $1,229,000 receiving building at the **Anoka State Hospital** were held on March 8. Governor C. Elmer Anderson gave the dedication speech. Conducted tours of the entire hospital were available to the public on March 8 and 9.

The new addition will house sixty patients—thirty women and thirty men—who will be new admittances. It is hoped that after diagnosis and intensive treatment, facilities for which are contained in the new building, most of the patients will require hospitalization for only a brief time before being returned to their own communities as useful citizens.

* * *

Open house was held at the new **Community Hospital** at Gaylord on March 15 and 16. Guided tours for visitors were conducted on both days.

The one-story, $225,000 structure contains twenty-two beds and a nursery. It is designed so that an additional wing can be added if necessary in the future.

* * *

Dr. F. W. Behmler, of Morris, is the new president of the State Board of Health, succeeding Dr. Ruth E. Boynton of Minneapolis. Dr. T. H. Sweetser, Minneapolis, is vice president of the Board. Dr. Behmler is a practicing physician who has always had a keen interest in public health. He has served as health officer in every town where he has practiced—Lafayette, Appleton, and Morris. He was appointed to the State Board of Health in 1940 and has been a member ever since. He was president of Minnesota Public Health Conference in 1950.

MINNESOTA BLUE CROSS-BLUE SHIELD PLANS

At a meeting of representatives of most of the Blue Shield plans in the United States, held in Chicago on February 28 and 29, methods of improving both public and physician relationship was the sole subject of discussion. Not only was it emphasized that the co-operation and support of the medical profession are vitally necessary for the continuing success of both Blue Cross and Blue Shield, but the value of physicians in selling both plans to subscribers and the public in general was stressed.

While the principles and purposes of both of these prepayment, non-profit plans are clearly understood by members of the medical profession, the public often reveals evidence of such fallacious thinking as expecting manifold returns on a relatively small investment. This attitude has been apparent over widespread areas as revealed in both correspondence and telephone inquiries. When time can be spent either by direct contact or by letter, clearly outlining the limitations of the Blue Shield contract, it is usually evident that the subscriber is satisfied.

Perhaps the most disturbing factor to the contract holder is the idea that he has a just medical claim, which fails to meet the contract requirements and is therefore ruled ineligible. The first reaction—either of anger or dissatisfaction—can usually be dispelled by painstaking explanation of the relevant sections of the contract and also explanation of the self-evident fact that an all-inclusive medical care contract would of necessity be so expensive as to defeat its own purpose. It becomes clear then that much of the public's criticism of Blue Shield stems not from the failure of the Blue Shield office to administer the contract properly, but rather from improper or inadequate understanding of the subscriber's investment, his Blue Shield contract. It is here that a few well chosen remarks by the doctor would help materially.

During February, 1952, Minnesota Blue Shield processed claims totalling slightly more than $310,000, the highest figure ever reached in Minnesota Blue Shield's four years of existence. Obviously with the increasing payment of claims, the public is likewise becoming increasingly aware of the value of its investment. This awareness becomes apparent in the increasing number

of thank-you letters received from subscribers for whom claims have been paid.

Recently, in an increasing number of claims, delayed processing and payment has resulted from receipt from the physician of only the original Medical Service Report. This delay can be avoided if both the original and one duplicate copy of the form is forwarded to the Blue Shield claims department. The triplicate or third copy only should be retained in the doctor's office.

During the year 1951, participation in the Minnesota Blue Shield Plan increased from 411,733 participant subscribers as of December 31, 1950, to 524,257 as of December 31, 1951.

Enrollment activity during the year 1951 resulted in 76,035 net additions to the number of Blue Shield contracts. The number of participating subscribers gained through these additions totaled 204,029 persons. Non-group enrollment campaigns carried on during 1951 resulted in the acquisition of 6,423 non-group contracts representing approximately 14,500 participant subscribers.

During the year 1951, Minnesota Medical Service, Inc., assumed the liability of $3,095,212.99 for 87,771 medical-surgical claims incurred by Blue Shield subscribers. These claims represented 490 claims per thousand contract years protected, an increase over 1950 of 59 claims per year per thousand contracts protected. Medical-surgical costs incurred during 1951 represented $17.26 per contract year protected compared with $16.54 during 1950.

Blue Shield participating doctors submitted 84,032 claims, or 95.7 per cent of total claims incurred during the year 1951, compared with 95.9 per cent during 1950. The medical-surgical cost of participating doctors' claims amounted to $2,934,410.02 or 94.8 per cent of the total medical-surgical costs incurred during 1951, compared with 94.9 per cent during 1950.

The classification of Blue Shield claims incurred during 1951 by type of service rendered reveals that medical claims totaled 21,723 and represented 24.8 per cent of total claims incurred, compared with 18,218 medical claims representing 31.1 per cent of total claims incurred during 1950.

Surgical claims during 1951 totaled 46,557 and represented 53.0 per cent of total claims incurred, compared with 34,338 surgical claims representing 58.6 per cent of total claims incurred during 1950. Total cost of surgical care incurred during 1950 amounted to $1,855,492.34.

During 1951, 87,771 Blue Shield claims were incurred or a total of 112,578 medical-surgical services were rendered to Minnesota Blue Shield subscribers. Of the total services thus incurred during 1951, 20.1 per cent represented medical care, 51.8 per cent surgical care, 9.6 per cent obstetrical care, and 11.2 per cent other services such as assisting after care, endoscopy and x-ray.

Blue Cross

Minnesota Blue Cross contracts in effect as of December 31, 1951, totaled 375,734 representing approximately 1,020,354 participant subscribers.

MINNESOTA REPRESENTATIVE—S. E. STRUBLE, WYOMING, MINN.

During the year, 166,538 participant subscribers or approximately 163 per thousand protected received hospital care. $11,312,390 or 88.8 per cent of income received from subscribers was used for hospital care.

Hospital care incurred during the year, 1951 including in-hospital bed patient and out-patient care, average 5.4 days per case.

The average length of hospital stay for single subscribers during 1951 was 7.1 days; for family participant subscribers the average was 5.2 days per case.

Maternity care totaling $2,279,907.62 representing 18.2 per cent of the total subscriber benefits protected during the year was incurred by 25,885 participant subscribers.

The upward trend in Blue Cross maternity incidence is the result of the record high in births reported in Minnesota during the year, 1951.

HENNEPIN COUNTY TUBERCULOSIS ASSOCIATION

Dr. Esmond R. Long, director of the Henry Phipps Institute, Philadelphia, delivered the seventeenth annual John W. Bell Tuberculosis Lecture, April 7, at the regular monthly meeting of the Hennepin County Medical Society at the North American Life and Casualty Building, Minneapolis. He was selected by a joint committee representing the Hennepin County Medical Society and the Hennepin County Tuberculosis Association.

Dr. Long is director of medical research for the National Tuberculosis Association and is a former president of that organization. For eight years (1942-1950) he was consultant on tuberculosis to the Surgeon General of the U. S. Army. He served with the occupation forces in Germany and organized the program to restore tuberculosis control measures in the civilian population of the U. S. Zone. He is consultant on tuberculosis to the U. S. Veterans' Administration, the U. S. Public Health Service, and the U. S. Indian Service.

His distinguished career as an international leader in tuberculosis control includes thirty-five years of teaching and research on tuberculosis, early studies of the chemical composition and growth requirements of the tubercle bacillus, certain phases of the pathogenesis of tuberculosis, direction of the national program of tuberculosis research and of the community health practice in tuberculosis at Henry Phipps Institute.

Dr. Long had a twofold subject for his lecture. As director of Phipps Institute, he discussed "The Changing Problem of Tuberculosis in a City Clinic." As research director of the National Tuberculosis Association, he gave a report (with slides) on results of use of isonicotinic acid hydrazide (INH), the new TB drug which has been recently publicized.

Choice of Dr. Long carried forward the record of distinction maintained by this lectureship since it was established in the Hennepin County Medical Society by the Tuberculosis Association in 1934. Outstanding leaders in tuberculosis work presented have included Dr. Gerald B. Webb, Dr. F. M. Pottenger, Dr. Leroy U. Gardner, Dr. David T. Smith, Dr. Herman E. Hilleboe, Dr. William H. Feldman, Dr. Haven Emerson and Dr. Joseph D. Aronson.

Members of the joint committee for the recent lecture were Dr. Russell H. Frost, Dr. H. E. Drill, Dr. Howard L. Horns and Dr. Asher A. White, representing the Hennepin County Tuberculosis Association, and Dr. Thomas Lowry, Dr. W. R. Jones, Dr. C. E. Merkert and Dr. C. R. Wall, the medical society.

Dr. W. R. Jones, president of the Hennepin County Medical Society, presided. Dr. Asher A. White, president of the Hennepin County Tuberculosis Association, introduced Dr. Long.

Dinner was served as usual at 5:45 p.m. Dr. Long spoke at 7:30 p.m.

FUNDAMENTALS OF PSYCHIATRY. Fifth Edition. Edward A. Strecker, M.D., Sc.D., LL.D., Litt. D., F.A.C.P. Professor of Psychiatry and Chairman of the Department, Undergraduate and Graduate Schools of Medicine, University of Pennsylvania; Phychiatrist to the Pennsylvania, Philadelphia and Germantown Hospitals; Consultant to the Surgeons General, U. S. Army and U. S. Navy, and formerly Consultant for the Secretary of War to the U.S.A.A.F.; Senior Consultant in Psychiatry, Veterans Administration; Consultant in Mental Hygiene, USPHS; Chairman, Committee on Psychiatry, National Research Council; Chairman, Committee on Psychiatry, American National Red Cross. 250 pages. Illus. Price $4.50, cloth. Philadelphia: J. B. Lippincott Co., 1952.

PLASTIC SURGERY OF THE NOSE. By James Barrett Brown, M.D., Professor of Clinical Surgery, Washington University School of Medicine, St. Louis, Mo.; Chief Consultant in Plastic Surgery, U. S. Veterans Administration, Wash., D. C.; formerly Senior Consultant in Plastic Surgery, U. S. Army and in E. T. O., and Chief of Plastic Surgery, Valley Forge General Hospital, and Frank McDowell, M.D., Assistant Professor of Clinical Surgery, Washington University School of Medicine, St. Louis, Mo. Price $15.00. 427 Pages. Illus. St. Louis, C. V. Mosby Co., 1951.

This book is unquestionably the finest publication yet to appear dealing with plastic and reconstructive surgery of the nose. The authors' eminence and vast experience in the field of plastic surgery is well known to all surgeons and is attested to by the excellence of the presentation of the material in this book. Not only is the work profusely illustrated with preoperative and postoperative photographs, but it contains many fine drawings by Miss Gertrude Hance depicting the surgical anatomy of the nose and the various maneuvers employed in the different operations. These plates are well integrated with the text, making it quite simple to understand the technical principles of the operations.

The authors first discuss the psychological considerations in plastic surgery of the nose and follow this by an evaluation of the reasons for operation. They then discuss the contour of the nose, normal and abnormal, telling what structural variations are responsible for the different nose shapes and what can be expected from repair. The section on the surgical anatomy of the nose with its discussions of the angles of the profile is unusually well done. Here the drawings of Miss Hance act as a powerful supplement to the text.

Next, there is a section dealing with the planning and designing of the operation. The part played by skin, by bone and by cartilage in the reconstruction is well explained. There is detailed discussion of the construction of plaster face casts, their use in the study of the deformity and in planning the operation. The use of photographs and measurements is discussed at length.

The section on operative techniques is unusually clear and is well illustrated with drawings and preoperative and postoperative photographs. The reasons for various techniques, the consequences of faulty techniques are explained so clearly that the author makes what is difficult seem very simple.

There is no slighting of the section on postoperative care, for the importance of this part of the treatment is emphasized. Finally, the authors round out the book with sections on the treatment of fractures of the nose, secondary repairs of nasal deformities consequent to cleft lips, and major reconstructive procedures necessitated by partial or total loss of the nose from various causes.

It is not possible in a book review such as this to describe adequately all sections of this book; however, it can be said that this work is an important part of the library of any person doing nasal plastic surgery.

(Continued from Page 357)

Hennepin County Medical Society. Dr. Corbett was also a member of the surgical staffs of Minneapolis General, Asbury, St. Mary's, Swedish, and Abbott Hospitals. His fraternities were Beta Theta Pi and Nu Sigma Nu. He was also a member of Sigma Psi.

Dr. Corbett's world-renowned collection of agates has been placed in the museum at Carleton College. His gun collection was given to the University of Michigan.

To within a few years of the end, Frank Corbett was a good and faithful servant to the University, the profession, and mankind. Many of us, who were his former students, shall miss him.

O. S. WYATT, M.D.

The following were elected as officers for the year 1952:

President	Dr. O. H. Wangensteen, U. of M.
Vice President	Dr. E. A. Regnier, Minneapolis
Secretary-Treasurer	Dr. Wallace P. Ritchie, re-elected

The President announced that Dr. Donald Balfour had requested that his name be placed on the Honorary Membership list, and the Executive Committee had approved this transfer. It was moved and seconded that this transfer be made. Motion was carried.

The scientific program followed.

DR. LEWIS THOMAS, University of Minnesota, by invitation, gave the paper of the evening, entitled "The Effect of Cortisone and ACTH on Infection." Lantern slides were shown.

The meeting was adjourned.

WALLACE P. RITCHIE, M.D., *Secretary*

From the standpoint of control, the most important characteristic of tuberculosis is the fact that it is communicable. In other communicable diseases like diphtheria, for example, for which we have dependable methods of immunization and effective therapeutic agents, the problem is entirely different and much more susceptible to control efforts. In tuberculosis, however, this is not the case, and the only sure way of checking its spread from one person to another is by finding and isolating the disease until it is no longer a danger to others.—ROBERT J. ANDERSON, M.D., Medical Papers of the Annual Meeting of the Canadian Tuberculosis Association, May, 1951.

the quality and dependability of PABLUM *cereals*

A multi-grain cereal and three single-grain cereals share the Pablum® heritage of quality.

Uniform texture, maximum digestibility and high nutritional values are assured by the careful Pablum processing.

Vitamins and minerals from natural sources are incorporated in Pablum Mixed Cereal, Pablum Oatmeal and Pablum Barley Cereal. Pablum Rice Cereal, with crystalline vitamins, has special advantages of hypoallergenicity.

Recent improvements in Mead's exclusive manufacturing process bring out more than ever the rich, full grain flavors of all the Pablum cereals.

Older children as well as infants will like these 4 cereals and welcome the variety they provide.

You may prescribe Pablum cereals with *confidence.*

Control capillary bleeding **in seconds**

A solution containing 1,000 units of THROMBIN TOPICAL per cc. will clot an equal volume of human blood in less than one second, or ten times this volume in three seconds.

Local application of THROMBIN TOPICAL produces hemostasis almost instantaneously, for this highly purified blood derivative acts directly on the fibrinogen to form a firm, adherent, *natural* clot. Whether you spray, flood or dust it onto affected surfaces, THROMBIN TOPICAL will help you to control capillary bleeding wherever found.

THROMBIN TOPICAL (bovine origin) is supplied in vials containing 5,000 N.I.H. units each, with a 5-cc. vial of sterile isotonic saline diluent. Also available in a package containing three vials of THROMBIN TOPICAL (1,000 N.I.H. units each) and one 6-cc. vial of diluent. Solutions of the product should never be injected.

"Conforming to the pattern of human milk"

Bremil®

for normal infant development

Clinical experience with thousands of infants demonstrates impressively the valuable role of Bremil in infant nutrition.

Bremil is a completely modified milk in which nutritionally essential elements of cow's milk have been adjusted in order to supply the nutritional requirements of infants deprived of human milk. It can be used with confidence either as part or all of the food supplied to the normal healthy infant.

Bremil conforms to the fatty acid and amino acid patterns of human milk. Bremil is a completely modified milk in which the calcium-phosphorus ratio (guaranteed minimum 1½:1) is adjusted to the pattern of human milk, thus helping to prevent tetanic symptoms in newborns.[1,2]

Bremil supplies the same carbohydrate as breast milk, lactose.[3]

Bremil's vitamin adjustments for standards of infant nutrition,[4] its human-milk size particle curd, miscibility and palatability are additional reasons for its choice in infant feeding. Bremil approximates the nutritional role of the mother.

Available in drugstores in 1 lb. cans.

FIRST RESORT
in NONSPECIFIC PROCTITIS *and* ULCERATIVE COLITIS

ACCEPTED
COUNCIL ON PHARMACY AND CHEMISTRY
AMERICAN MEDICAL ASSOCIATION

Negative results with certain other forms of therapy have prompted many physicians to turn to NISULFAZOLE as a "last resort"— only to discover that it should have been their first approach to NONSPECIFIC ULCERATIVE PROCTITIS and COLITIS.

NISULFAZOLE frequently brings striking initial improvement in these cases . . . reduction in number of stools often occurring within the first 24 hours. Administered intrarectally, NISULFAZOLE exerts "focal" action at the site of the disease. The high incidence of remission of symptoms following NISULFAZOLE therapy is a source of gratification to physician and patient alike.

Meat and its applicability in the Dietary Management of Atherosclerosis

Contrary to the former belief that serum cholesterol levels are primarily related to ingested animal fat and consequently to dietary cholesterol, it now appears that the total amount of fat in the diet, not its source or cholesterol content, is a more important factor in determining the blood cholesterol concentration.[1,2,3,4] Clinical observation has shown that ingestion of vegetable fat—which contains no cholesterol—will, like fats of animal origin, raise the serum cholesterol level.[3, 5]

Recent basic research on the influence of fats and cholesterol on human health has done much to further progress in the fight against atherosclerosis. It will serve well in dispelling the mistaken fear that reasonable amounts of foods of animal origin predispose the individual to this vascular disease.[6] As a matter of fact, a dietary inadequate in essential nutrients but providing too many calories and too much fat from *any* source may well be an important factor underlying the deposition of fat and cholesterol in the arteries and liver.

Cumulative evidence indicates that lowered blood levels of cholesterol may be effected by restricting the total fat intake.[1] Except in instances of refractory hypercholesteremia, in which a daily fat intake as low as 10 Gm. may not reduce cholesterol levels to normal, diets containing 20 to 30 Gm. of fat, or even more, often produce low cholesterol blood levels. In the clinical application of this principle, various palatable, low fat diets which supply three servings of meat daily (containing 18 Gm. of fat) have recently been suggested for the dietary management of arteriosclerosis and for enlisting the cooperation of patients.[1] The meat servings were chosen from a large variety of cuts and kinds of meat (fat trimmed off, as lean as possible). Meat adds to the eating appeal of the fat-restricted diet and contributes important amounts of biologically complete protein, the B group of vitamins including B_{12}, and food iron—all of which are important for a good state of nutrition in the atherosclerotic patient.

protein? 60%

yet as acceptable to the patient as a tasty milk shake

When the protein intake must be increased beyond the amount an acceptable diet can supply, **H.P.S.** *Sixty* proves especially valuable. Providing 60% protein, 1.5% fat, and 27% carbohydrate, it makes a delightful beverage with water or milk, readily acceptable to the patient even when anorexia prevails.

Prepared with water according to directions (6 oz. water, 1½ oz. **H.P.S.** *Sixty*), three servings daily furnish 77 Gm. of biologically complete protein. When skim milk or whole milk is used instead of water, three servings provide 96 Gm. or 95 Gm. of protein respectively.

H.P.S. *Sixty* is processed from milk protein concentrate, soy protein, whole egg powder, powdered sugar and flavoring. Its proteins are intact; hence it is not burdened by objectionable odor. Valuable for use when whole protein can be utilized, **H.P.S.** *Sixty* may be indicated in the dietary management of undernutrition, peptic ulcer, hepatitis, chronic diarrheal states, pregnancy and lactation, and following burns and other injuries which raise the protein needs. Caloric equivalent, 3.6 per Gm., 102 per ounce.

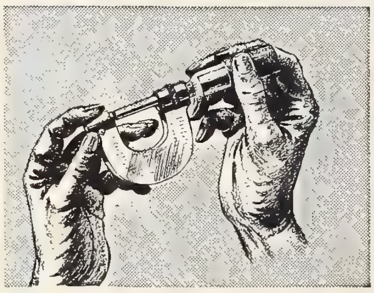
Cortone®

Can Put Your Arthritic Patients
BACK TO WORK

INITIAL DOSAGE:
25 mg. four times daily. Consult literature for detailed dosage recommendations.

STEP-WISE REDUCTION:
After moderate relief is established, reduce daily dosage step-wise every three or four days, to smallest suitable maintenance level.



MAINTENANCE DOSAGE:
25 to 50 mg. daily has been found adequate in more than 50 per cent of a series of patients.

Conservative dosage in rheumatoid arthritis provides effective relief—and often may be continued for long periods

Individualized dosage, careful clinical observation, and simple, readily available laboratory procedures (sedimentation rates, urinalyses, blood counts, blood pressure, and frequent weight recordings) are adequate for the rehabilitation and management of most patients.

CORTONE is the registered trade-mark of Merck & Co., Inc. for its brand of cortisone. This substance was first made available to the world by Merck research and production.

citrus is a good

ANORETIC

agent

When taken about half an hour before meals, orange or grapefruit juice is highly effective in helping overweight patients to adhere to their reducing regimens. Citrus has "very definite advantages"* as an appetite appeaser. It helps to reduce the demand for high caloric foods, and supplies readily utilizable carbohydrates to combat hypoglycemia. It is economically available in homes or restaurants. And, of no small consideration, most everyone likes orange or grapefruit juice.

From among all antibiotics,
Obstetricians and Gynecologists often choose

AUREOMYCIN

Hydrochloride Crystalline

Because
Aureomycin diffuses so rapidly that it becomes available immediately to all the tissues in and about the pelvis.

Aureomycin readily passes into the blood stream, and through the placenta into the fetal circulation.

Aureomycin may be given by the oral, or in an emergency by the intravenous, route.

Aureomycin has been reported clinically effective when used systemically against susceptible organisms in many gynecologic and obstetrical infections, including:
Parenteral and Post-partum Infectious Complications • Mastitis • Thrombophlebitis • Pyelitis of Pregnancy • Staphylococcal Infection in the Newborn

Throughout the world, as in the United States, aureomycin is recognized as a broad-spectrum antibiotic of established effectiveness.

Capsules: 50 mg.—Bottles of 25 and 100; 250 mg.—Bottles of 16 and 100.
Ophthalmic: Vials of 25 mg. with dropper; solution prepared by adding 5 cc. of distilled water.

Ciba Summit, N.J. 2/1728M

Now
another important advantage of Thiomerin:

Wyeth®

Suitability for Home Administration

The self-injection of the thionated mercurial diuretic, Thiomerin, has now become a well-established procedure for patients who have congestive heart failure, just as the self-injection of insulin has long been a well-established procedure for patients who have diabetes.

Numerous authorities[1-12] recommend Thiomerin for home administration because it is as well tolerated and predictable in effect when given *subcutaneously*, as when given intramuscularly and intravenously. The technique of injecting Thiomerin Sodium may be quickly mastered.

Consequently, more and more physicians are finding that it is often desirable to instruct the patient or a member of his family in the use of Thiomerin so that injections between visits can be made on schedule—according to the dosage plan that best suits each patient.

A supply of *printed instructions for patients* will be sent to the physician on request.

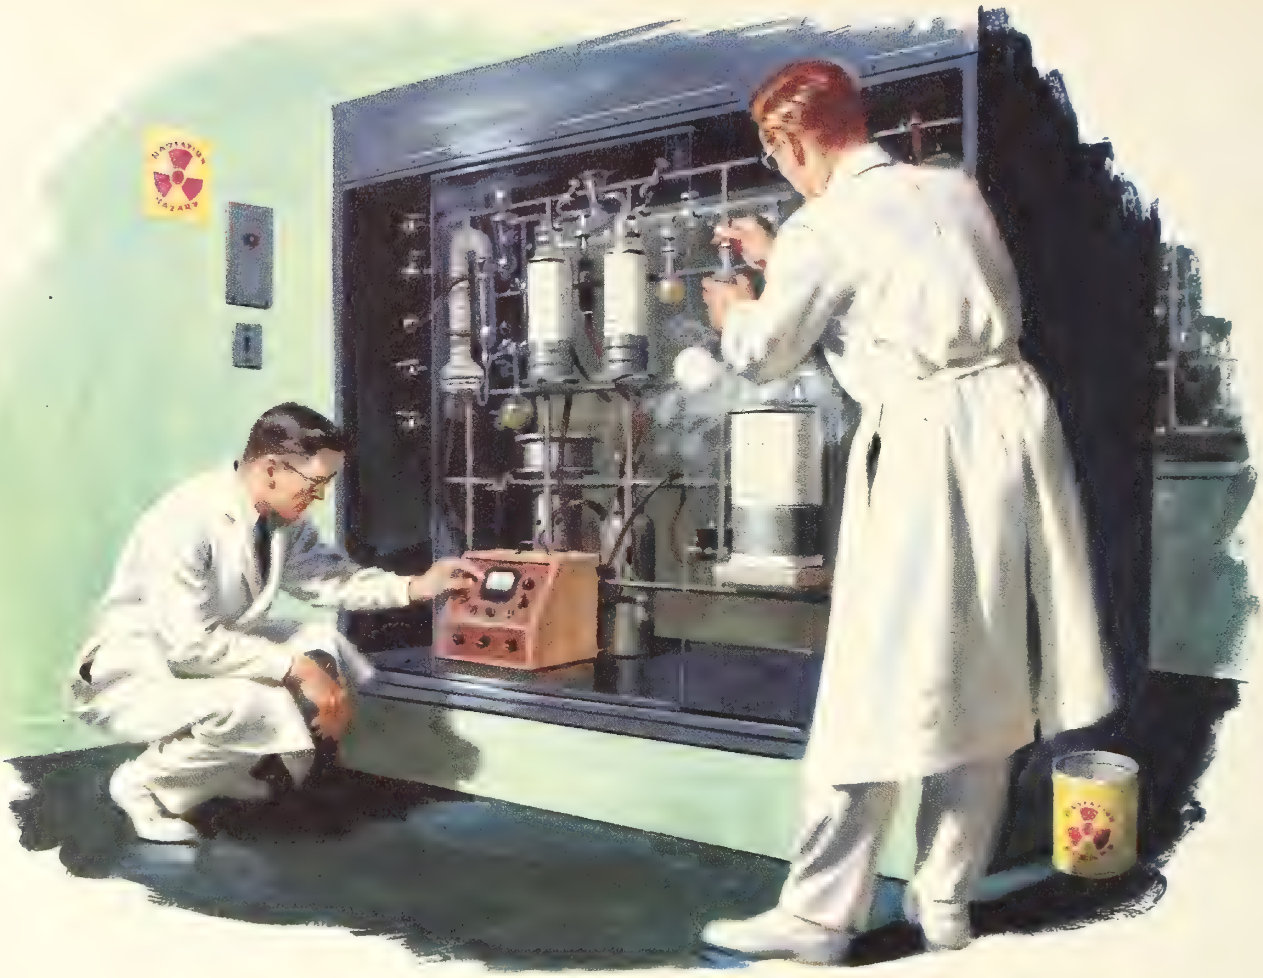
With the help of his overworked patience and a flashlight, Dr. Harris finally locates the house from which an urgent summons has interrupted his sleep. Although he may find only unnecessary alarm, he will bring the family nothing less than restored confidence.

With another light, his critical judgment, he long ago found a pharmaceutical house in which he could place his confidence. He is not only sure that the products are all that the labels claim, but he is certain that the future of medicine is bound to benefit from a company which reaches out into such new avenues of investigation as . . . →

Doctor Harris finds the right house

Lilly



. . . tracer studies

Among the most constructive new tools with which medical research may benefit humanity are the radioactive isotopes. Paradoxically, these became available through the discoveries in nuclear fission that led to the production of the atomic bomb.

By radioactively labeling substances and following the course that they take in the body, Lilly radiochemists are now able to tackle fundamental problems that were formerly totally insoluble. The results that have already been obtained from studies of this type are impressive. Wholly new conceptions of many biochemical processes are emerging. When we consider that these methods are still in their infancy, we may well believe that eventually many baffling diseases may surrender to this new power.

This is an outstanding instance of how research in one field of science is being joined with that of others in the Lilly Laboratories. Here, physicists work hand in hand with chemists, physiologists, pharmacologists, and clinicians for a common goal—the progress of medicine.

PSYCHIATRIC IMPLICATIONS OF THE ATOMIC AGE

WILLIAM HOWARD HENGSTLER, M.D.

Saint Paul, Minnesota

WE LIVE in strenuous times. The world faces its greatest crisis. Speed, which has been viciously catapulting all mankind for the past three or four decades, has finally brought us to the point where man has devised an instrument which, if used, can destroy both himself and civilization. Since 1914 there has been war, peace, a severe depression, another war, a semblance of peace, and finally a war which is said not to be a war. Millions of bewildered humans have followed the kaleidoscopic chain of events, unable to understand the why and wherefore of it all. They have been led down one road and up another, through conflict and peace, and back again, until they can no longer maintain emotional poise or emotional stability. They have seen ideologies come and go, and governments rise and fall. They have seen freedoms revoked or restricted, their money devalued, and in some places their wealth confiscated, their property taken away, and their friends and relatives liquidated. Through it all the cry of the instigators has been for power and more power, speed and more speed, armanent and more armanent, money and more money.

And we call this the Atomic Age!

To all of this, repercussions of one kind or another have been inevitable. America has never before been confronted with problems like those of today. To be sure, this nation has passed through severe crises, like those of 1776 and 1865. But those were pertinent, for the most part, to America alone and bore no special relationship to the world at large. Today we find ourselves in the middle of an international and world-wide muddle such as never before existed.

This presentation has no political tinge and is not a criticism of anyone. It is an unbiased analysis of conditions that exist today, by one who has been interested in human relationships for a third of a century. In America we are having powerful social repercussions to the Atomic Age. These concern our entire population.

The greatest effects of this social repercussion are upon our young people. Because of the necessity of the draft, and of almost universal military service, our young men can no longer make definite or specific plans for their own lives. Education may be interrupted or postponed, careers may be changed or eliminated, and marriage with a home and family and a normal settled life may be made more difficult or impossible. In addition, there is the threat of death or disability on the field of battle. The young women of our country are affected directly by the predicament of the young men. They must wait to marry, or marry and wait for their men to return to them. In wartime, and to some extent today, there has been much doubling up of families. The housing shortage, or other reasons, have made it expeditious for the wives and children of service men to live with their own or their husband's parents, with many resultant conflicts and maladjustments of one kind or another. All of these conditions induce a sense of futility and hopelessness, and a feeling of confusion and deep resentment in the minds of many of our younger generation.

Older persons, especially the parents of our service men and women, have had the added burden of anxiety over the safety and welfare

---

Presidential Address delivered before the Minnesota Academy of Medicine, January 9, 1952.

of their sons and daughters, and have been dismayed by the apalling growth and magnitude of their problem. As a result of all of this, we are having a definite social upheaval in this country, characterized by a great variety of mental and emotional reactions in our population. Never before in America have people felt so generally maladjusted or so generally insecure as they feel today.

When we examine the economic repercussion to the Atomic Age in this country we find it shown most clearly by inflation and increased taxation. Devaluation of our currency, with the great loss in the purchasing power of our dollar, has severely jarred the security of most of our people. No longer is a good income of the 1940 vintage an adequate income for today. Rising living costs with failure of income to increase proportionately have required economies and budget revisions never before deemed necessary. Organized labor, because of its power, has been able to make income keep pace with living costs to some extent. But consider the plight of the white collar worker, of the man retired on a pension or a fixed income, and of the man who is trying to live on an annuity purchased twenty or thirty years ago! With no Union or organized force behind them, their lot is indeed a sad one. In addition, taxes have now moved up to an all-time high, to decrease further the buying power of the income of every person. Many older or retired persons, in order to augment an insufficient fixed income, decide that they must go back to work again. But when they go out and try to get a job they are told that they are too old and that there is no work for them. In the eyes of most employers of today, useful life now ends at forty instead of beginning there. And so economic repercussion has had its effect upon our population, and adds to the general demoralization of emotions, and to the tendency toward unrest and dissatisfaction, which exist in our land today

A third important repercussion is in the field of politics. For the past twenty years the United States has had a national government which has gradually tended to develop centralized power in the nation's Capitol. Slowly but surely this government has subtracted from free enterprise and so-called rugged individualism, until today we stand where no one two decades ago realized that we could stand. Through the mediums of gradually increasing power over the lives of all of us, and through the mechanism of progressive increase in taxation of all kinds, we as individuals are now stripped of practically all opportunity to create or amass for ourselves a fortune, or even a competency for our old age. Our conception of America, particularly those of us in the older generation, has always been a land of opportunity for all comers. A poor immigrant boy could come to this country and if he possessed the business ability to make a fortune, or to become successful, he was allowed to do so. Apparently with present economic conditions and government controls, such opportunities no longer exist. For twenty years we have been governed by a single dynasty. It is disturbing that in a democracy any one political party, no matter which one, could have the strength to stay in power for that length of time. That does not conform to the idea of true democracy. Our government has become an accepted thing and many members of our younger voting population cannot remember any other political party being in power. They have accepted the idea of a centralized government with both a taking and a giving hand reaching out toward them, and they have had a tendency to feel that the government owes them something, that they do not have to be particularly anxious about working or making their own way, because if they cannot do it the government always will or should help them, and this has become their primal concept. This is an attitude that has gradually crept into the minds of our youth during the past twenty years as a result of the benevolences of different kinds that have been handed out from our nation's Capital. The effect of all this is most apparent on the people of the older generation who had once experienced the pleasure of living in the days of more individual freedom and of more uncomplicated governmental functions. They resent the drift toward a welfare state. The younger generation have never known anything different than that which we now have and so they are not particularly annoyed by the tribulation of comparison. They have become indoctrinated with the idea that the government will or should take care of them, and so they have a fair sense of indifference as to the amount of their own effort that they should expend.

At the present time the international political situation tends to produce mixed emotions in most people. The gradual shift of this country from isolation to active participation in world affairs has brought about a great variety of controversial reactions in our population, and the financial debacle with money waste and the rise of our national debt to astronomical figures, has not tended to promote a feeling of security among the people. On top of this recently have come the sordid tales of corruption in some branches of our government which further promotes the loss of faith and a decreased feeling of confidence. From what we have been hearing the past few weeks about graft in certain branches of our government, we are led to believe that the code of "what's in it for me" runs deeper than "what can I do for my country."

Through the medium of the radio the world has become a very small place. A few decades ago, the Emperor of China, or the ruler of Russia, could speak and say what they pleased and we never knew it, or cared about it, unless it was of enough importance to appear in the press. But today, let one word drop from the lips of the Sultan of Zulu and it is flashed around the globe within the hour, to the confusion perhaps of many thinking persons. The regular appearances of our radio commentators at definite stated intervals, has also added to the general conflict in the minds of our population. Each commentator has his own ideas as to what is wrong and as to what should be done, and the contradictory broadcasts from one day to another are extremely unsettling to the emotions of the average individual. The heartbreak of Korea has given a large percentage of our people an active and anxious interest in what is going on in that country, and the rather conflicting reports which come daily from the battle front, and the constant arguments back and forth as to whether or not there will be an armistice, and the recent publication of the Communists' lists of United Nations' prisoners, are factors of no mean strength in causing restlessness, and uneasiness, and emotional tension among the people concerned. They are perplexed and unsure and they would like to have some leadership that would give them some definite idea as to just why all this is going on and as to just what they can expect as far as the future of their young men is concerned. There is almost certainly a feeling among our people that they are not being told everything and that they do not know exactly what the policies of the United States are insofar as the war in Korea is concerned.

The inevitable result of a situation of this kind in a nation is to bring about moral repercussions, and those of us who keep pace with moral conditions in America, know that today we are having a period of moral repercussions. Crime is much more prevalent. The papers are filled with accounts of holdups, murders, kidnappings, and various other types of misdeeds. It takes us back to the days of the roaring twenties when the mobs were in control of everything. Today there is not so much mob control but apparently there is another wave of moral turpitude sweeping over this nation. Young people are committing crimes of all kinds. Sex crimes are rather prevalent, and deviations from normal in the conduct of many people are observed by those in a position to see them. It is true that under the surface in this country there is apparently big-time crime, even as it was back in the 1920's, although probably of a little different type. The Kefauver Committee as publicly reported, has uncovered plenty of evidence of rings of crime, largely financial types of crime, rather than murders and kidnappings such as we experienced twenty-five years ago. Stories of graft and corruption in government are pouring out daily through our news disseminating media. Men in high places are branded as crooks and cheats. A pattern is developing, showing how widespread has been this dishonesty throughout our entire nation. To our consternation we learn that high officials in our government are said to be just common crooks. And what effect will this have upon the population? It will add to their emotional demoralization. It will add to their suspicion and unhappiness and will subtract from their faith and confidence in that government that collects their taxes.

Then there is the problem of alcohol. This is our major national social problem today. Unrest, insecurity and the resultant emotional instability, have precipitated an alarming increase in alcoholism. People are drinking to escape reality. Confronted with the problems they find insurmountable and insoluble, they escape in the temporary euphoria of alcohol. This applies to many persons in all age groups. Those of the older generation try to escape from the insecurity they feel in the economic and social spheres. Those of the younger generation seek stimulation to escape the frustrations they are experiencing as a result of the previously described restrictions that interfere with the calm and successful pursuit of their ambitions and their lives.

In addition to the problem of alcohol, there is the problem of drugs, both narotic and non-narcotic. Recent publicity has bared extensive use of narcotics, even among teenage school children. But far more prevalent is the widespread use of non-narcotic sedative medications. It is disquieting to know the large number of people who believe they must have a drug to make them rest, or to make them sleep, or to "quiet their nerves." How many of our profession know the psychological value of a capsule of common salt or sugar, prescribed for the neurotic patient, who must have something to take at bedtime, so he can sleep! Fortunately some legal restrictions have been placed upon the sale or dispensing of these drugs. But it is disturbing to know how many people think that they need something of this kind in order to live a normal and happy life. Others seek stimulating drugs, to pep them up so they can face their lives and their problems realistically. All of this proves the unsettled emotions in many persons of today which must have chemical support so as to present an artificial semblance of stability in living.

Lastly, let us consider the spiritual repercussions. There is no question that the emotional status in America today has produced spiritual reactions. The psychiatrist sees the patients who have never before been spiritually upset, people who have been of the Christian faith and who have calmly and serenely gone through life, who as a result of all the happenings in the world today, have become disturbed, and in connection with that disturbance begin to doubt their own spiritual status. Relatively soon these persons are in a highly muddled and confused emotional state centering around their relationship to God and their chances of salvation after death. I think it can be said that we are meeting in psychiatry more such cases today than we ever have met before, not only among older people, but among our young generation. We are seeing many of the younger generation who have come face to face with the problem of whether or not they wish to believe in a God and in the tenets of Christianity. This question begins to revolve around them with such speed that before long they are confused to a point where they do not know their own minds and develop various types of reactions, and eventually land in the hands of the psychiatrist. Religious leaders in this country are somewhat at a variance in regard to their opinions as to whether or not there is an actual increase of spiritual attitude among the people. Some authorities on religious matters feel that more people are turning to churches today than ever before. Other just as competent authoritities in this field say that this is not true, but that more people are feeling the need of it than ever before. Evangelism on the radio has become a very popular thing, and according to newspaper accounts, in some instances has resulted in the conversion of large numbers of people. Whether such conversion by these Evangelists represents an actual stable acceptance of religious principles and Christian faith on the part of the converted people is problematical. Many times emotionally upset people turn on the spur of the moment to a spiritual solution of their problem, which later is not acceptable to them because they have had a chance unemotionally to think it over. However, it is true I believe, that church membership rolls are not increasing at this time. This I think is admitted. So there are both types of spiritual repercussion to the present things going on in the world of today. On the one hand there are the people who feel the need of the security of Christian faith and belief in God. On the other hand is the reaction of people who have been of the Christian faith but have begun to doubt whether or not they really are Christians, and whether or not they really do stand in the desired relationship to their God.

The combined effect of all the factors that have been outlined naturally result in emotional trauma for a large portion of the people in this nation. The basic emotional reaction is in the realm of fear. Fear is our most powerful emotion and when aroused can produce more undesirable effects in an individual than any other one of the emotions. I think it can safely be said that in the world of today, both in this country and abroad, there has come to exist a state of fear never before known. This is not the fear of any specific thing; it is simply a state of fear that something is going to happen, they do not know what. We are living in the age when we are told daily of the threat of the atomic bomb. We are told how to try to prepare a defense against the atomic bomb. Then we are told that there is no de-

PRESENT-DAY TREATMENT OF BURNS

MARK B. COVENTRY, M.D.
Rochester, Minnesota

THE PROBLEM of burns had its origin when prehistoric man first learned to use fire and today, in spite of tremendous advances in our medical knowledge, the burned patient still presents a challenge to the skill of the physician. Medical history reveals the use of countless local applications of supposedly healing substances, but the understanding of the basic disturbances in body metabolism which occur when the patient is burned, and the subsequent treatment of that patient, are far more important than local therapy. A milestone in the treatment of burns took place in 1925 when Davidson,[4] working at Henry Ford Hospital, began using tannic acid in an endeavor to reduce the loss of plasma, diminish cutaneous infection, and decrease pain. The chief objections to its use were the occurrence of secondary infection underneath the eschar, gangrene due to the constricting eschar, and central necrosis of the liver, which occurred rather more frequently when tanning agents were used. Other local applications such as picric acid and gentian violet were used after the discovery of tannic acid. In 1942, Allen and Koch[1] reported the use of sterile dressing with a petrolatum base, combined with pressure. This treatment has been the one of choice since that time and has only recently been challenged in favor of the open or nondressing technique.[3,8]

In general, increased knowledge of body metabolism and its changes during the burn stages and the ability to combat these changes have led to a decided decrease in mortality rates. The death rate from severe burns at Toronto Children's Hospital[5] showed a decrease from 11.8 per cent in 1938 to 2.9 per cent in 1941. This decrease followed the appreciation of plasma loss and its replacement, the use of sulfonamide drugs and the use of cortin. The latter substance has since been shown to be ineffective in preventing shock—but the appreciation of loss of fluids, changes in electrolyte balance, and chemotherapy and antibiotic therapy of infection has reduced the death rate in cases of severe burns to a surprisingly low figure.

War has greatly influenced the treatment of the burned patient. Trueta,[7] after the suggestion of Zeno,[10] applied the principles of occlusive dressings and immobilization achieved by the plaster of paris bandage in the Spanish Civil War. The British used these methods at Tobruk during World War II. The burns experienced in England proper during World War II included those of the face and hands suffered by aviators, and the British developed a rather specialized method of treating the burned hand. We in America were plunged into the problem of burns at the time of the bombing of Pearl Harbor. The use of tanning agents was just then being questioned, and following Pearl Harbor our technique changed to the application of petrolatum to the burn, over which was placed a massive pressure dressing. Two catastrophes in the continental United States, namely the Coconut Grove fire in Boston in 1942 and the Ringling Brothers Circus fire in Hartford, Connecticut, in 1945, added to our experience in and knowledge of the management of the burned patient. The new problem of atomic burn occurred toward the end of World War II.

Definition and Stages of Burns

Only by defining a burn as an injury to the body as a whole and to the skin in particular are we able to comprehend its full importance. Whether burns result from heat, cold, electricity, chemicals, sun rays, roentgen rays or atomic rays the ultimate problem is the same. We must recognize the three stages of a burn in order to treat it properly.

1. *Shock.*—The first stage of a burn, that of shock, lasts from twenty-four to forty-eight hours. It is not materially different from other forms of shock and is characterized by a fall in blood pressure, a rapid pulse, cold extremities and hemoconcentration.

2. *Toxemia.*—Toxemia persists from the end of the stage of shock for four or five days thereafter. The term "toxemia" is used for want of a better one. There may be some form of toxic element generated or liberated by the body which

---

From the Section of Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

seems to be present during this stage. Recently Moyer[6] has postulated that this stage is due to water intoxication and not toxemia, and he has been able to prevent the toxemic phase in dogs with proper attention to electrolytes and fluid. During this period there is evidence of parenchymatous damage associated with oliguria, headache, vomiting, drowsiness and fever. Renal damage is most obvious and most profound. A pronounced increase in the nonprotein nitrogen content of the plasma occurs. Changes may occur in the central nervous system during this stage of toxemia, accompanied by convulsions and coma. The liver, spleen, and gastrointestinal tract are damaged.

3. *Anemia and Hypoproteinemia.*—This third stage of a burn was formerly called the "stage of sepsis," but with the use of antibiotics infection has been materially decreased. Anemia and hypoproteinemia remain, however, as definite entities. During the third stage epithelization occurs and skin is grafted when necessary.

Treatment

The treatment, then, of a burn depends on the stage of the burn. When the patient is first admitted to the emergency room of the hospital, an evaluation of the seriousness of the burn must be made. Patients with burns of small area, or of superficial degree can be treated as outpatients. Those with burns involving a surface equal to that of one upper extremity or more, however, should be hospitalized and the burns should be considered as serious. Patients having burns of more than first degree which involve the hands or feet should likewise be hospitalized. The patient should be wrapped in a sterile sheet after his clothing has been removed. Blood pressure should be taken and recorded. Morphine should be given to relieve pain, but excessive amounts should be avoided for they increase the danger of an already impending general collapse of the circulatory system. One-sixth grain of morphine administered hypodermically is usually enough. Tetanus antitoxin or a booster dose of toxoid should be administered. If shock is present the patient should be treated immediately for this condition. Treatment consists of administration of whole blood, plasma or plasma substitutes. Hemolysis occurs very early after burning, causing a reduction in the number of erythrocytes. A proportionately greater amount of plasma is lost into the burned area. The general feeling today is that more whole blood should be used than has been used in the past, and in the case of a serious burn administration of as much as 2,000 cc. often is indicated during the first twenty-four hours of treatment. Oral administration of fluids is best if tolerated, giving 3 to 4 gm. of sodium chloride and 1.5 gm. of sodium bicarbonate per liter[6] for the first three or four days. This supplies the necessary electrolytes and prevents water intoxication. If fluids cannot be taken orally Hartmann's solution administered intravenously gives satisfactory results. The intake of salt orally or intravenously should be decreased in three to four days or edema will develop.

The next problem is that of local treatment of the burned area. Débridement is generally unnecessary. It adds to the shock of the patient and is frequently contaminating. If large particles of dirt are present these can be removed, but removal of all of the burned epidermis is of no value to the patient. A decision must be made as to whether to treat the burn in an open or a closed fashion. The closed method, which consists of pressure dressings applied over petrolatum-impregnated gauze, has many advantages. Patients are generally comfortable in this type of dressing, for it acts as a splint to the extremities, preventing motion at the joints. In the past it has been thought that this method prevented the loss of plasma, but this probably is not so. Wallace,[8] Blocker and others[2,3] have recently revived the use of the open method of treatment for burns. The burns are not dressed, but the patient is laid on sterile sheets in bed, preferably covered with a canopy to prevent drafts. There may be less disturbance in electrolyte balance by this form of treatment. Because there are no dressings to change, proponents of this method claim the treatment is less painful and less expensive. Their figures also seem to indicate that the period of hospitalization is shorter and less infection occurs when the open method is used. The mortality rate is the same for either type of treatment. During mass catastrophe, each form of treatment has its beneficial points. A community might exhaust its supply of large bulky dressings necessary for pressure bandaging, but the same community also might not have enough hospital beds for its patients. It is true that in time of catastrophe many patients, especially those whose burns do not involve more than a fifth or a quarter of the bodily surface, frequently can be treated as ambulatory or semiambulatory patients. Bandaging allows the ready transportation of such patients. If hospital beds are available it would seem that the open method of treatment, when the burn is extensive enough to prevent home care and transportation, is the method of choice.

The treatment for burns in the second stage, namely that of toxemia, is one of replacement. Fluid balance should be carefully studied. There is no simple index to follow, but the patient must be treated for changes in the body chemistry and fluid balance as these changes occur. This is done best by oral administration of fluids. The concentration of chlorides tends to decrease but should be kept at 600 mg. per 100 cc. of plasma if possible. The concentration of sodium and of potassium ions also decreases and should be replaced. The carbon dioxide combining power should be checked and corrected when and if acidosis occurs. The prevention and treatment of suppression of renal function is the main problem during this stage and the intake of fluids should be adequate to meet the situation, avoiding water intoxication as Moyer[6] has indicated. Vitamins, especially ascorbic acid, should be administered during the second stage of burns. Enough water should be taken to maintain a urinary output of 1,200 cc. daily if possible, but overloading with tap water may cause water intoxication. Enough protein should be administered to keep the concentration of protein between 6 and 7 gm. per 100 cc. of blood. This is best accomplished by feeding high protein diets, which include meat, powdered skim milk, and meat soups. These also provide needful potassium ions. If necessary, a formula can be administered by gastric tube. Further protein can be given intravenously in the form of hydrolized protein, blood and plasma, but that given orally is the most readily and efficiently utilized by the body. Glucose should be administered in adequate amounts. It has been estimated that about one and a half times the basic caloric requirement should be given to the burned patient after the first week of treatment.

Treatment during the third stage, that of anemia and hypoproteinemia, includes transfusions of blood, oral intake of iron, a high protein intake by mouth, and as early skin grafting as possible.

Antibiotic Therapy

Antibiotic treatment or chemotherapy should be started from the beginning. Penicillin is probably the antibiotic of choice and 600,000 units of procaine penicillin can be administered daily. This should be used regardless of whether the open or closed method is employed. Cultures of the burned areas should be taken and if organisms are discovered which are not sensitive to penicillin, one of the other antibiotics can be used. Antibiotic therapy should be continued until the skin grafts have taken and open ulcers are no longer present.

Skin Grafting

It is easy to say that skin grafting must be done early but it is often difficult to carry this out. The cases of burns are few, however, in which skin cannot be grafted by the end of the third week.

If the closed method of treatment has been used dressings are usually done weekly and at the end of the fourteenth day it is usually possible to determine whether the burns are of second degree and will heal by themselves or of third degree and will require grafting. If they are of third degree, one must wait for the eschar to demarcate, but not necessarily separate, for it can be excised surgically. Infection can usually be controlled with antibiotics. Usually special preparation of the ulcerated areas for skin grafting is not needed, but daily baths with sterile saline may be given or saline dressings can be applied before operation if the areas are not clean.

As a rule skin grafting is done best by the split-graft technique, removing large areas of skin with a dermatome and either suturing them in place, or using them for the "postage stamp" type of graft when suturing is difficult or undesirable. The dressings are left for seven days before changing.

If the burn is of such an extent that skin grafting cannot be done because enough autografts are not available, homografts can be used. These may take well for a matter of weeks, but will then slough. The use of cortisone and corticotropin (ACTH), either or both, has not increased the possibility of "take" in homografts.[9] Pedicle grafts are reserved for areas over bony prominences or tendons, but should not be applied until these are first covered with split-skin grafts. Correction of deep scars and contractures can take place at a later date.

Cortisone and Corticotropin (ACTH)

The initial reports on the use of cortisone and corticotropin in the treatment of burns were most encouraging. My colleagues and I have used these hormones in the treatment of several severely burned patients, and we have formulated some opinions regarding their use. These opinions are more or less tentative, and it should be strongly emphasized that the use of cortisone for severely burned patients is still in an investigative stage. First of all, it seems to be of definite value in the first stage, that of shock. We have seen patients survive with as much as 80 per cent of the surface of their bodies burned, and we feel that cortisone and corticotropin were instrumental in this survival. Secondly, the stage of toxemia seems to be unaffected by cortisone or corticotropin. Use of the hormones therefore can be discontinued once the patient is out of shock. During the third stage of a burn, namely, that of anemia and hypoproteinemia, cortisone and corticotropin seem to have little or no beneficial effects, and, therefore, should not be given at this time. There may be improvement in appetite, but no other visible benefits, and there is no evidence to show that they increase the rate of epithelization.

At least three side effects may occur if cortisone is used in the treatment of burns. The clinician must be aware of these possibilities and must weigh the advantages already mentioned against these possible complications. They are as follows:

1. Adrenal suppression may occur, and it has occurred when relatively small doses have been given for only a few days. This means that the surgeon must fully protect his patient with cortisone during any operative procedure. If the patient has received cortisone during the stage of shock, he must be protected by the administration of cortisone before, during, and after any skin grafting procedure during the third stage of the burn.

2. Cortisone has an effect on peptic ulcers. In cases in which cortisone is given, the incidence of peptic ulcers and the complications of existing peptic ulcers are increased. We, however, have not observed a higher incidence of Curling's ulcer.

3. Cortisone may suppress the usual signs and symptoms of intercurrent infections. Careful observation for bacteremia or localized infection should be made, and the patient should be given appropriate antibiotics if cortisone is used.

According to some reports in the literature, cortisone will allow successful skin grafting if the patient is "sensitive" to his own skin. In at least one case at the Mayo Clinic, however, in which we felt that the patient was sensitive to his own skin, cortisone did not help. Certainly in the usual case cortisone does not increase the chance that an autogenous skin graft will take, and, as mentioned previously, it will not cause a homograft to survive.

Summary and Conclusions

In order to treat a burned patient properly the physician must realize that a burn is an injury to the body as a whole as well as to the skin. There is no index or easy plan for the treatment of all burns. He should be cognizant of the three stages that the burned patient passes through, know what takes place during these three stages, and institute adequate replacement therapy day by day. The benefits of the open and closed methods are still being argued. The use of cortisone or corticotropin seems indicated in the treatment of severely burned patients during the shock phase, but these hormones should be used only when the condition of the patient can be carefully followed in respect to metabolism and fluid balance.

PANCREATITIS

HENRY FISKETTI, M.D.
Duluth, Minnesota
FREDERICK SCHNELL, M.D.
Virginia, Minnesota

OCCASIONALLY in the practice of medicine syndromes which are comparatively rare may be frequently encountered. When this transpires, one first wonders as to the accuracy of his diagnosis and his interest in the particular subject is aroused. In the past it has been my medical good fortune to see within a short space of time several patients with pancreatitis of different gradation or phase of involvement. Therefore a general analysis of all cases in the records of St. Mary's hospital in Duluth was instituted by one of us (Schnell) and a comprehensive discussion of pancreatitis has been undertaken. I am sure that the majority of cases at the hospital have been diagnosed in recent years, since the advent of the serum amylase determination; but that those cases diagnosed in earlier years were labelled such, not while the patient lived and still could have benefited from a correct diagnosis, but by autopsy studies of the astute Dr. Berdez. This is just another instance of a disease for which we have a fairly specific diagnostic laboratory aid. It is also paradoxical and incredible that this same specific serum amylase determination is so seldom used as a laboratory aid in the evaluation of obscure cases of acute intra-abdominal disease.

Before beginning a general discussion of pancreatitis, it was deemed advisable to give a very brief review of the histology and of the physiology involved. The pancreas has both an internal and external secretory function. The external is manifested by the activity of the acinar cells in producing pancreatic juice, which plays a major rôle in the digestion of proteins, fats and carbohydrates. The internal secretion, now known as insulin, is formed in the islet cells and passes into the portal blood stream where, in the liver, it plays its essential role in carbohydrate metabolism.

The pancreatic juice, as it is emptied from the ampulla of Vater into the duodenum, is a limpid, alkaline, colorless fluid, with a pH of 7.1 to 8.2. It is not secreted at a uniform rate, but varies with the emptying of acid gastric chyme into the duodenum. The mucosa of the duodenum and upper jejunum when stimulated by acid chyme, liberates into the blood stream a substance called secretin, which in turn stimulates the flow of pancreatic juice when it reaches the acinar cells in the pancreas. This is the hormonal factor in the external secretion.

A second factor controlling the flow of pancreatic juice is nervous stimulation by way of the vagi. Vagal control regulates the concentration of the coenzymes in the juice, whereas secretin stimulates the qualitative flow, causing an increase in the fluid and salt content of the juice. Thus there is a double control of pancreatic external secretion, which must be considered and understood in any discussion of the laboratory tests of pancreatic function.

The ferments of pancreatic juice are trypsin, chymotrypsin, amylase, lipase, renin and maltase. Unlike the gastric enzymes, apparently those of the pancreatic juice are produced by one type of cell. There are at least two proteinases in pancreatic juice: trypsin and chymotrypsin. Trypsin is not secreted as such, but in an inactive form called trypsinogen. The activation was first shown in Pavlov's laboratory to be brought about by the addition of a small quantity of intestinal juice or extract of the intestinal mucosa. The activation is due to an enzyme called enterokinase. There has been some discussion as to whether this is a true enzyme, but there is no doubt that its enzymic nature is now accepted. Trypsinogen may also be activated by physiochemical methods in the laboratory. Chymotrypsin is also secreted in an active form called chymotrypsinogen, and is activated by enterokinase but not by trypsin. These two enzymes, trypsin and chymotrypsin, are mainly responsible for the proteolytic activity of pancreatic juice. Trypsin has no milk-curdling power, but is capable of clotting blood, whereas chymotrypsin, although it will not cause coagulation of blood, has a powerful milk-curdling action and is probably identical with pancreatic renin. The action of trypsin carries the digestion of protein beyond the peptone stage. It also differs from peptic digestion, being carried out in an alkaline instead of an acid medium. Trypsin commences its action after the gastric juice has converted a large part of the protein into proteoses and peptones. Experimentally, flesh introduced directly into the duodenum is readily digested by the pancreatic juice. Specific action of trypsin is to break the proteose and peptone fragments of the protein molecule into smaller amino acid groups. These are generally termed peptides. Further complete breakdown of protein is reserved for the erepsin of the succus entericus in the bowel.

Pancreatic amylase or amylopsin or diastase has an action similar to but much more powerful than that of salivary amylase or ptyalin. In the hydrolysis of starch by pancreatic juice, the starch is converted into maltose within a very few minutes. It is important to remember, in connection with infant feeding, that during the first few weeks of life, the pancreatic amylase, the only really efficient ferment for the digestion of starches, is absent from the pancreatic juice. Therefore, little provision has been made for the digestion at this time of any other food than milk. The amyolytic ferment of the pancreas finds the chloride ion absolutely essential for its action, and acts best when the medium is faintly acid and neutral. Fat is not digested to any important extent until it has reached the intestine. Here the lipase splits the fat molecule into its constituents, fatty acids and glycerine. A certain proportion of the fatty acids combine with the alkaline intestinal fluids to form soaps. These, through their property of lowering surface tension, aid in the division of the fat into smaller globules. Bile salts have a similar and important effect upon the emulsification process and, therefore, greatly enhance the fat-splitting action of steopsin or pancreatic lipase. Pancreatic renin has an action similar to that of gastric renin. Pancreatic juice has a much more powerful milk-curdling power than has gastric juice. It is probable that the action is not due to a separate enzyme but to chymotrypsin.

A discussion of the historical background and the physiological principles involved in the action of insulin is not within the scope of this paper. The literature in recent years contains much material attempting to correlate the functions of the liver with those of the pancreas and the relation of pancreatic function to some of the degenerative changes, fatty and otherwise, in the liver. I am sure that all of us have long ago made the observation that many diabetics have some impairment of liver function and even an hepatomegaly. In the laboratory, completely depancreatized dogs observed over a period of 10 to 12 weeks, regardless of insulin therapy, show, among other lesions, a severe fatty infiltration of the liver. Hershey felt that the administration of large daily doses of lecithin had a sparing effect on this liver degeneration and Brest and his associates claim that this effect is due to the choline content of the lecithin. It has also been shown in experimental animals and in clinical cases, that a complete pancreatic fistula, with total exclusion of pancreatic juice from the gastrointestinal tract, results in marked dehydration, electrolytic imbalance and death within a period of two to six weeks. There is shown loss of plasma base, urine chlorides, bicarbonate, a shift to the acid side of the pH, increase in non-protein nitrogen and urea in the blood. We therefore see how closely related diseases of the liver can be with disturbed pancreatic function.

We shall first concern ourselves with acute pancreatitis. This term includes several types of acute inflammatory processes: the lesions caused by the escape of the enzymes of the pancreatic juice through the acinar cells as a result of obstruction; secondly the lesions caused by bacterial invasion and the so-called apoplexy of the pancreas—the result of a rupture of a large vessel with sudden severe hemorrhage into the organ. These processes may merge one into the other, but the pathogenesis of the different types is now better understood.

The first clear-cut correlation of the gross pathology and symptomatology of acute pancreatitis was made by Reginald Fitz in his classical monograph in 1889. He, however, did not distinguish the pathogenesis of the several varieties. Opie, in 1901, described a case of acute pancreatitis in which the flow of infected bile into the pancreas from the common duct, due to a stone impacted in the ampulla, popularized the "common-channel" theory of the etiology of the lesion. Others have cited that the incidence of dilatation of the pancreatic duct was no greater in patients with fat necrosis than in the control group, suggesting that pancreatitis is not explained by a lesion leading to duct obstruction.

Several experimental studies have been made in an attempt to explain the pathogenesis of acute pancreatitis. In one, a series of experiments on sixty-four cats was carried out to show the influence of ligation of the pancreatic duct, of starvation, of feeding and of secretin and pilocarpine injections. It was clear that ligation of ducts alone in a starved animal was not followed by necrosis. However, obstruction in the fed animal or in the animal whose pancreas has been stimulated by either secretin or pilocarpine, led to varying degrees of fat necrosis. Indeed, working on cats, Elman and Butcher showed that when the pancreatic ducts were ligated and the animals were fed, they showed evidence of fat necrosis between 48 hours and 6 days, even though no pancreatic stimulus by a drug was given.

In the second study, carried out on dogs and rats by a variety of injections into the pancreatic duct, either with or without ligation, it was shown in general that activated pancreatic juice, particularly when the duct is ligated, produces pancreatic necrosis, an observation which has been made many times in the past.

One of the most provocative studies was the third, which seemed to show one manner in which pancreatic edema may be converted into pancreatic necrosis. Pancreatic edema was produced in all experiments by means of duct ligation followed by the stimulation of the pancreas with secretin injections. However, in addition to this, in ten dogs, using seven as controls, varying degrees of occlusion of the main pancreatic artery were produced in a period of fifteen minutes. In each experiment, pancreatic necrosis followed the vascular occlusion and the degree of necrosis varied with the degree of edema present before the arteries were occluded. Inasmuch as vasospasm is known to follow as a reflex action from pain, these experiments seem to have a real clinical application by suggesting the need for prompt control of pancreatic pain.

In another study, Archibald showed that by producing a spasm of the sphincter of Oddi and by increasing the bile pressure, an acute pancreatitis could be produced in a certain percentage of animals. Dvagstad and his co-workers brought forward evidence to show that the lesions in pancreatitis were caused by the combined action of bile salts and anerobic bacteria.

The controversy regarding the pathogenesis of acute pancreatitis is still active, and Rich and Duff, in 1936, published experimental studies that seemed to establish the exact pathology of the vascular changes caused by the escape of pancreatic ferments between the acinar cells into the interstitial tissue of the organ with subsequent hemorrhage, digestion and necrosis of the organ. Some of their observations were on the vascular changes which result from trypsin digestion and they suggested that the activity and the concentration of trypsinogen or trypsin determines the degree of edema and the extent of vascular damage. However, it is another way of explaining the discrepancy in symptomatology and operative findings which vary from a mere edema of the pancreas to the extensive hemorrhage and necrosis of the organ in the severe fatal cases.

The escape of pancreatic juice into the interstitial tissue may cause edema, fat necrosis and vascular necrosis with hemorrhage, depending upon the concentration and activation of the lipolytic and proteolytic ferment of the escaping juice. With edema the symptoms are as a rule milder and the damage is quickly repaired. No doubt the metabolism of a certain number of cells is interfered with to the point where they die. Since the introduction of serum amylase determinations as a diagnostic test of acute pancreatic duct obstruction, it is now recognized that many cases of mild and even severe epigastric pain and tenderness are associated with edema of the pancreas or of scattered areas of fat necrosis, for when operated upon at the time, days or weeks later, the evidence of areas of fat necrosis are found. The majority of patients with this type of edema or interstitial pancreatitis recover with conservative treatment.

From the above brief discussion on the pathogenesis of acute pancreatitis, it can readily be appreciated what the pathologic findings in the cases of acute pancreatitis will be and that they are directly dependent upon the concentration and extent of the destructive process within the pancreas. Pathological findings vary from a diffuse edema of the head or all of the pancreas to slightly elevated areas of pinhead size to 1 cm., ivory-colored, fat necrosis in the omentum and fatty tissue around the pancreas; to patchy or diffuse areas of hemorrhagic infiltration or necrosis of part or of all of the organ. In the cases with hemorrhage and necrosis, a sanguinous fluid is usually found in the peritoneal cavity, especially around the pancreas and the lesser sac.

It is obvious that the degree of hemorrhage and necrosis of the organ determines the severity of the symptoms of the vasomotor collapse that is so characteristic of a severe lesion. These latter symptoms follow the absorption of a split protein product of the trypsin itself. The shock is related to what is known as peptone shock in experimental animals. The changes in the fluid and electrolyte balance associated with the profoundness of the shock, make any surgical procedure very hazardous. In the past when these cases were considered immediate emergencies, the operative mortality was prohibitively high.

The cardinal symptoms of acute pancreatitis are pain, nausea and vomiting. The general symptoms of acute pancreatitis may exactly simulate those of other conditions producing acute abdominal distress. Usually, the onset and course of the disease are such as to make the case fit one of the following five descriptions. I am sure that almost all of us at one time or another have been in attendance on a patient with pancreatitis and that in retrospect, you will agree that he came under any one of the five following clinical syndrome patterns.

Group I.— This type is characterized by the sudden onset of a severe, excruciating upper abdominal pain, commonly occurring in an elderly, obese, florid male, who has eaten a large meal several hours previously, preceded by several highballs. Immediately following the onset of pain, nausea and usually profuse vomiting occur. The patient is in profound shock with cyanotic, mottled skin, diffuse tenderness and minimal to severe rigidity of the abdomen. Ecchymosis or bluish discoloration in either or both flanks or about the umbilicus may subsequently occur. Death commonly follows in 48 to 70 hours, in spite of all forms of therapy directed at control of the acute pancreatitis. This is the usual textbook description of the disease, but fortunately this group represents only a small percentage of the cases. Into this group also fall those patients with symptoms simulating those of acute coronary occlusion, with pain in the left upper quadrant of the abdomen or in the precordium.

The remaining four clinical picture patterns, which are representative of the more common forms of the disease, are not sufficiently emphasized in the standard textbook.

Group II.—This syndrome simulates that associated with acute cholecystitis, with sudden onset of moderately severe epigastric or right upper quadrant abdominal pain, which may radiate through to the back or around the right costal margin to the back. The onset of pain is followed by nausea and vomiting, usually moderate in amount, sometimes profuse. Occasionally there may be associated mild or moderate jaundice, which further confuses the clinical diagnosis. This particular group is representative of those cases of acute pancreatitis involving primarily the head of the pancreas. In such cases the patient is in the early course of the disease and may be relieved of symptoms by the use of right paravertebral blocks.

Group III.—In this group the symptoms are typical of acute mechanical small intestinal obstruction. The patient may have intermittent generalized rhythmic, cramp-like abdominal pain, associated with nausea and vomiting, with both clinical and x-ray evidence of distention of the small bowel. Patients in this group usually present no obvious cause for the obstruction, such as an external hernia or abdominal scar. Commonly present is a physical finding which is normally not present in intestinal obstruction—this is flank tenderness, either unilateral or bilateral, which is caused by retroperitoneal extravasation of pancreatic fluid. In the past, the largest number of mistaken diagnoses was among patients in this classification. It is now routine to determine blood amylase and urinary diastase in all cases of apparent mechanical small intestinal obstruction at some clinics.

Group IV.—The picture is that of acute alcoholism with acute gastritis, characterized by upper abdominal pain with nausea and profuse vomiting. These symptoms may be mild to severe. This group commonly includes patients diagnosed as slow, leaky peptic ulcer, induced by a recent bout of alcoholism. Because of the known high incidence of acute pancreatitis associated with or during acute alcoholism, the diastatic activity is determined routinely at Los Angeles County General Hospital in any case in which an alcoholic patient is admitted with abdominal symptoms.

Group V.—This group includes those cases in which the patient has a mass in the epigastrium or left upper quadrant of the abdomen. Such patients frequently give a history of having had an attack of abdominal pain with nausea and vomiting three or four weeks previously. This represents an attack of acute pancreatitis which has progressed into one of its complications: a pseudocyst, a collection of exudate in the lesser sac or rarely a pancreatic abscess.

Associated Symptoms.—Diarrhea is also an associated symptom and in one series occurred in twenty-two out of 307 cases. It is a symptom also which may cause confusion with the picture of acute gastroenteritis or enterocolitis. Another associated symptom may be gastrointestinal hemorrhage. Its presence may be manifested by blood in the vomitus or in bloody diarrhea. In going through the literature, this symptom has not been found to be very common and the same holds true with the St. Mary's series.

The diagnosis can sometimes be made from the history alone, as most cases will fall into one of the previously described groups. The physical findings vary considerably according to the stage of the disease and the severity of the process. Practically all patients have moderate to severe abdominal tenderness, most pronounced in the epigastrium, right upper quadrant or left upper quadrant of the abdomen. Later in the disease there may be diffuse abdominal tenderness after the extravasation of bloody fluid from the pancreas into the peritoneal cavity. The patients commonly have unilateral or bilateral flank tenderness and this finding is rarely present in other acute conditions of the abdomen. There will also be a bluish discoloration or ecchymosis in either flank, which is known as Turner's sign, or rarely a bluish discoloration or ecchymosis about the umbilicus. This is known as Cullen's sign.

With regard to the diastatic activity, the blood amalyse becomes elevated within the first twenty-four hours in acute pancreatitis, and frequently remains normal for the first twelve to eighteen hours. The amylase then remains elevated for twenty-four to seventy-two hours, depending upon the severity of the disease; but frequently returns to normal before clinical subsidence of the process. It is very important to know this because if this fact is not known, occasionally a presumptive diagnosis of acute pancreatitis will be changed merely because the serum amylase determination was normal, whereas in reality had this determination been made within the first seventy-two hours, it would have been markedly elevated and would corroborate the presumptive diagnosis. Urinary diastase commonly does not increase until twenty-four hours after the increase in blood amylase, but remains elevated twenty-four to forty-eight hours longer than the amylase. As these time elements are not constant and the reverse may occur, Paxton and Paine, of Los Angeles, recommend the simultaneous use of both tests in any suspected case of acute pancreatitis. We must not forget that there are other non-important causes for increase of amylase; and recently it has been thought that morphine could cause an elevation of the serum amylase, so it would be wise to draw the blood for this test immediately on admission.

Roentgenologic studies as an aid in the diagnosis of pancreatitis are not very helpful. They may show a segmental ileus of any section of the gastrointestinal tract, but this occurs most frequently in the transverse colon. X-ray study is purely of negative value, but naturally will be most valuable in differentiating pancreatitis from any condition resulting from perforation of a hollow viscus.

The blood calcium may be lowered due to the utilization of the ionizable calcium, which combines with the fatty acid in the formation of calcium soaps, a process indicated by the characteristic areas of fat necrosis. Recognizable lowering of the calcium occurs, however, only in the moderate and severe stages of the disease. A low level of calcium is probably most useful in diagnosis in the case of patients in the late stage of the disease after diastatic activity has returned to normal.

The treatment of choice in uncomplicated acute pancreatitis is non-surgical. For this reason it is important that physicians be alert for acute pancreatitis so that the diagnosis may be made early clinically rather than at the time of surgical exploration.

Basic in the conservative treatment of acute pancreatitis is to put the pancreas as nearly at rest as is physiologically possible. To this end, treatment should include: (1) continuous nasal gastric suction; (2) adequate sedation; (3) adequate and regular use of atropine sulfate; (4) sufficient parenteral fluids to maintain water and electrolyte balance; (5) possible arterial antispasmodics. Following the work of Truetta on the role of arterial spasm, Paxton and Paine have been using paravertebral blocks, either unilateral or bilateral, depending upon the clinical location of the disease. Intravenous novocaine was used and more recently, epidural block. Epidural block has certain advantages. It requires the use of only one injection site and it interrupts the sympathetic as well as the sensory fibers, which gives the patient immediate relief of pain. Splanchnic block is also effective. The use of continuous nasal gastric suction produces several desirable effects:

(1) It gives the patient symptomatic relief by controlling vomiting.

(2) It prevents the acid gastric secretions from entering the duodenum, thus reducing the hormonal stimulation of the pancreas to a minimum.

(3) It prevents acute gastric dilatation and helps control ileus. One important fact in the non-surgical treatment is to continue nasal gastric suction at least twenty-four hours after the temperature has returned to normal. When the suction is discontinued too early, an acute exacerbation commonly occurs. To me it would seem that absolute control of the severe shocking pain that is so characteristic of acute pancreatitis is absolutely essential. I think that none of us would deny that pain is also a very important contributing element in the production of shock, and inasmuch as shock, in addition to the so-called foreign protein or peptone shock element of pancreatitis, is the main cause of death in those cases of acute hemorrhagic pancreatitis, I think you will agree that abolishing pain is not only humane but one of the best points of treatment.

The food and caloric requirements are met by giving 3,000 to 4,000 cc. of 5 per cent glucose solution intravenously daily. No insulin is given unless there is associated diabetes. In passing, it is also important in patients with acute pancreatitis, to determine the blood sugar, because it is at this time that some of them become diabetics and intelligent management and treatment depend to a great extent on whether diabetes is superimposed or not. In cases in which prolonged nasal gastric suction is necessary, frequent determination of the carbon dioxide combining power, the blood sodium and potassium are necessary.

Atropine sulfate is given in large doses, .6 to .8 mgm. regularly every three to four hours. This is done to suppress the vagus effect on the pancreas. Vagus stimulation produces pancreatic juice rich in enzymes. Atropine also produces some degree of relaxation of the sphincter of Oddi. Morphine sulfate is given regularly to control the pain of pancreatic necrosis. The morphine also decreases the activity of the gastrointestinal tract. Penicillin in adequate dosage may be and has been used and is only of questionable value.

Although it is felt that a cholecystogram should be made routinely following an attack of acute pancreatitis, in severe cases, acute exacerbation has developed immediately following x-ray of the gallbladder. Therefore, some authors now postpone this procedure until at least 8 weeks after an acute attack. In mentioning parenteral fluids in the treatment of pancreatitis, I neglected to state that transfusion of blood or plasma may be given as indicated. I could find nothing in the literature on the use of the newer synthetic substances intravenously in severe shock states.

If, with improvement in pulse and blood pressure on the above conservative treatment, the patient continues to have severe pain and signs of spreading peritoneal irritation, and especially if jaundice appears or serum bilirubin shows a rising figure, surgery is indicated. Proper procedure is to sidetrack the bile by cholecystostomy and to relieve intra-abdominal pressure and drainage of the peritoneal exudate. The former procedure of attempting to incise the capsule of the pancreas and to puncture the organ for drainage purposes results only in further damage to the pancreas and is to be condemned. A cholecystostomy and cigarette drains to the area of the inflamed pancreas should be the limit of the operation. If the patient improves and does not show evidences of bile blockage, he should be treated conservatively and watched for a localized suppurative process. The development of an abscess may take several days or even weeks, and is indicated by the usual signs of abscess formation, such as rising or persistent temperature, persistent leukocytosis and a localizing area of tenderness over the head, body or tail of the pancreas. With this localization of an abscess, operation for drainage is always indicated. In no type of case is wholehearted cooperation between the physician and surgeon more essential in the proper management.

Prognosis is variable. In the patients who fail to respond to conservative therapy and require operation, the mortality is necessarily high, varying from 10 to 30 per cent. In a series of sixty-two patients operated upon at Presbyterian Hospital between the years 1916 and 1941, the mortality was 29 per cent. In a smaller number, not operated upon, the mortality was 17 per cent. Series reported by Elman and Butcher, St. Louis, 27 per cent of those treated conservatively died, including those who were admitted in extremis; and of over 100 cases operated on, there were 46 deaths, or a mortality of 44 per cent. From personal experience and from a study of the literature, the general impression is gained that conservative therapy for acute hemorrhagic pancreatitis is still the treatment of choice in most cases. In the very severe fulminating lesions with hemorrhage and necrosis, the cause of rapid death is not explained. Profound shock, no doubt, is a factor. Archibald found areas of focal necrosis in the liver of experimental animals in whom death occurred as early as half an hour after the production of hemorrhagic pancreatitis. Some Irishman in Dublin reported a group of thirty-one patients in whom the rapid death and the absence of any obvious cause required a coroner's inquest. There was a history of drinking in all the cases, but the only constant lesion was found in the pancreas and was that of necrosis; so we see that acute pancreatitis or pancreatic necrosis can lead to sudden death although the exact mechanism of the same is not exactly understood.

I would like to mention briefly a few statements concerning chronic relapsing pancreatitis. This is a term not used until Comfort, Gamble and Blankenstoss, in 1946, presented studies of twenty-seven such cases. It is their contention that a chronic relapsing pancreatitis is a disease of recurrent acute episodes of severe abdominal pain which are progressive and gradually become so severe and so frequent as to be intractable. It is not a common disease, approximately twenty cases being encountered each year in the early 1940's at the Mayo Clinic. It is now more frequently recognized than it was formerly. Curiously, it predominates in the male, 6 to 1. Patients who have the disease are usually not obese. In these last two respects it differs from disease of the biliary tract. It is more common in patients in middle age and in alcoholics. There are certain findings that strongly suggest that chronic relapsing pancreatitis is not necessarily secondary to disease of the biliary tract, but may be, and frequently is, independent of it. These men have shown that grossly the pancreas is indurated and sometimes nodular and that microscopically fibroblastic proliferation and fibrosis are prominent features. Gross atrophy of the gland, pseudocyst formation and macroscopic calcification are characteristic of the disease. Interstitial fibrosis and residual necrosis of tissue are other constant findings. It appears that this form of pancreatitis may be responsible for dilatation of the gallbladder and that the degree of pathological change in the gallbladder and ducts has some relationship to the extensiveness and activity of the disease in the pancreas. Recurring acute severe prolonged exacerbations of upper abdominal pain separated by intervals of relative or complete clinical quiescence are characteristic of the disease. Pain is the outstanding clinical feature of the acute attack and is usually steady and frequently and characteristically it radiates to the left upper quadrant of the abdomen to the back. Intervals between attacks vary greatly. It may be years in the early stages of the disease. As the disease progresses, the intervals shorten and become marked by persisting digestive symptoms, signs of disturbance of pancreatic function and, at times, by diabetes. In the interval between attacks there are frequently no symptoms in the early stage of the disease. In approximately half the cases observed by Comfort, pronounced permanent sequelae including diabetes, steatorrhea and calcification of the pancreas were present and observable in the interval between acute painful exacerbations of the disease. Laboratory data obtained during acute attacks may reveal leukocytosis, acceleration of the sedimentation rate and evidence of jaundice.

The following phenomena, if present, are useful in substantiating the diagnosis: elevation of values for amylase and lipase in the serum and of the value for fecal solids, fat or nitrogen in the stool by chemical analysis; grossly fatty stools and excessive amounts of fat by microscopic examination. In some cases in which accurate studies can be made of the value of the bicarbonate and enzymatic concentration of duodenal content after stimulation with secretin, the finding of values lower than normal may be useful in substantiating the diagnosis. X-ray studies may reveal multiple areas of calcification throughout the pancreas. However, the course followed by the patient may be diagnostically important because it may be typical showing acute, severe prolonged upper abdominal pain associated with transient elevations in value of serum lipase of amylase and perhaps hyperglycemia during the attack. This is generally followed over a period of years by more

MENINGITIS DUE TO SIMULTANEOUS INFECTION WITH MYCOBACTERIUM TUBERCULOSIS AND A STAPHYLOCOCCUS

Report of a Case

SCOTT N. SWISHER, M.D.
Rochester, New York

MENINGEAL infections in which two organisms can be isolated simultaneously from the spinal fluid are uncommon. In a recent comprehensive review of this subject, Riley[4] collected thirty-three well-documented cases of dual infection from the world literature since 1911 and added an additional case of coexisting meningococcal and tuberculous meningitis. Riley's case is apparently the first type of a dual infection of this type reported in the American literature. It is the purpose of this paper to present a case of simultaneous meningeal infection with Mycobacterium tuberculosis and a Gram-positive coccus which was probably an altered staphylococcus. This combination of infecting organisms was not found in the cases collected by Riley from the world literature.

Case Report

I. E., an eighteen-year-old single white girl, was first seen at the Ancker Hospital in July, 1946, when she was admitted to the Obstetrical Service at the termination of an apparently uneventful pregnancy. General physical and laboratory examinations at that time disclosed no significant abnormalities. She was delivered of a normal male infant after a normal labor. The postpartum convalescence was rapid and complete and she was discharged apparently well.

In January of 1947 she was employed as a maid and elevator operator in a tuberculosis sanatorium where she worked for two months. Her contact with patients having open pulmonary tuberculosis was limited to serving of food and cleaning duties under the usual isolation technique. During this period, she had no apparent change in health.

She was next seen on May 25, 1948, when she was admitted with the chief complaint of enlargement of the lower abdomen for three months. There was some variability in the degree of the enlargement from day to day. She had experienced two short attacks of sharp, non-radiating pain in the lower abdomen at the onset of the abdominal enlargement. She admitted that she had had a moderate amount of creamy vaginal discharge since the birth of her child two years previously. For two weeks prior to her admission, she had noted a low-grade fever, especially in the afternoon, with symptoms of malaise, fatigue, and anorexia during the period of temperature elevation.

Her past history revealed only the usual diseases of childhood, a tonsillectomy, and an appendectomy at age eleven. She had had a mild non-productive chronic cough for several months. Her weight had been maintained. There was no history of further contact with tuberculous patients.

Physical examination at this time revealed a temperature of 100 degrees F. and a pulse of 100 per minute. She was comfortable and did not appear ill. The mouth showed many severely carious teeth. The chest was entirely normal to physical examination. The heart was normal in size and shape. The mitral first sound was broadened and roughened. There was a short, soft, blowing, apical systolic murmur which was not transmitted. The abdomen was enlarged below the umbilicus with a soft, bulging, non-tender mass which seemed to be distended small bowel. No organs or other masses were palpable, bowel sounds were normal, and signs of peritoneal irritation were absent. Pelvic examination revealed tubal thickening and tenderness bilaterally with a slight amount of creamy vaginal discharge.

At this time the urine, hemoglobin, and red blood cell count values were normal. The white blood cell count was 5,600 per cu. mm. with a normal differential count. A Friedman test for pregnancy was negative. A cervical culture and smear were negative for Neisseria gonorrhea. The sedimentation rate was 41 mm. per hour. A roentgenogram of the chest was normal.

For the first six weeks of hospitalization, her temperature varied between approximately 101 degrees and 103 degrees F. orally with a few frank chills during this time. Her cough became more prominent. She was treated with penicillin, 80,000 units intramuscularly every three hours for a week without response. She was given sulfadiazine for three days until all medications were discontinued because of the possibility that drug intolerance might be responsible for the continued fever. There was no change in the clinical course, and penicillin in doses of 100,000 units intramuscularly every three hours was again administered for four days without clinical effect.

During this interval, a white blood cell count was 4,500 per cu. mm. with a normal differential formula. A battery of serum agglutination studies were negative on several occasions. The Mantoux reaction was negative to 1:10,000 and 1:1,000 dilutions of old tuberculin.

Two weeks after admission a roentgenogram of the chest revealed minimal bilateral pleural effusion and some congestion and infiltration in the right lung base.

Formerly Medical Fellow, University of Minnesota, and Chief Medical Resident, Ancker Hospital, Saint Paul, Minnesota, Dr. Swisher is now associated with the Department of Internal Medicine, University of Rochester School of Medicine and Dentistry, Rochester, N. Y.

A hematologic study revealed normal hemoglobin and 6,250 white blood cells per cu. mm. with 71 polymorphonuclears, 20 lymphocytes, 3 monocytes and 6 eosinophils per one hundred cells. A thoracentesis removed 100 cc. of straw-colored fluid from the right pleural cavity, but unfortunately this material was lost prior to examination. A blood culture was sterile. Repeated roentgenograms of the chest during the following 4 weeks showed resorption of the fluid on the left with persistence of the fluid on the right and no change in the appearance of the lung parenchyma.

The patient then began to feel poorly with recurring anorexia, nausea and vomiting. She became irritable, depressed and unco-operative and took on much of the appearance of chronic illness. The abdominal enlargement persisted, and gradual development of an indefinite mass of somewhat firmer consistency extending from the pelvis to the level of the umbilicus was noted. Pelvic examinations showed an enlarging, slightly tender, firm, cystic feeling mass lying in the cul-de-sac and adnexal regions bilaterally, with induration extending into the anterior vaginal wall.

Colpotomy and culdoscopy were performed, but the pelvic organs could not be visualized due to adhesions and inflammatory reaction. On June 30, 1948, she was again given penicillin therapy, 100,000 units intramuscularly every three hours. Sulfathiazole was given for a period of one week. Twelve days later she became afebrile. Coincidentally, she began to feel much improved and was gradually mobilized without event. Pelvic examination at this time showed persistence of the mass with a decrease in tenderness and induration. On July 19, 1948, she was discharged. She was seen in the Out-Patient Clinic on three occasions during the two months following discharge. She complained of some intermittent lower abdominal pain, but had had no fever and felt well. The sedimentation rate on one visit was 28 mm. per hour.

The final hospitalization occurred on September 15, 1948, when she was admitted complaining of constant frontal and occipital headache which had begun suddenly twelve days previously. A stiff, sore neck and back developed about ten days before admission. She had had moderate general malaise, nausea, and vomiting since the onset of the headache. The day before the onset of this illness, a severely carious, infected third molar had been removed and five days later another similar third molar had been extracted. The extractions seemed uneventful. Two days before admission she noted the onset of transient tinnitus and blurred vision with photophobia. On the day prior to admission she felt a vague, transient weakness of the left arm.

Physical examination at this time revealed a temperature of 102.4 degrees F. orally, a pulse of 90 per minute and respirations of 20 per minute. The blood pressure was 110/70. She appeared acutely ill, tense, apprehensive, emotionally unstable, and dehydrated. The eyes, including funduscopic examination and the ocular movements, were normal. The ears, paranasal sinuses, nose and throat were normal. The right lower and upper left third molars had been recently removed. The sockets appeared healthy and healing. The neck was rigid to flexion and pain was severe when this was attempted. There were moderate decrease of resonance to percussion and diminished breath sounds over the right base posteriorly and laterally upon examination of the lungs. The cardiac findings were unchanged. Neurological examination revealed no cranial nerve abnormalities. There was no localized muscular weakness. Sensation was normal except for a vague hyperesthesia over the left half of the body. Co-ordination was normal. The deep tendon reflexes in the upper extremities were normal and in the lower extremities were absent. There were no Hoffman or Babinski signs. There was marked limitation of straight-leg-raising bilaterally with pain and spasm of the paraspinal muscle groups.

At this time the white blood count was 9,500 per cu. mm. with 89 polymorphonuclears, 10 lymphocytes and 1 monocyte per 100 cells. The urine obtained following a glucose infusion showed 1 per cent glucose and 1+ acetone, but was otherwise normal. A lumbar puncture showed an initial pressure of 230 mm. of spinal fluid, and a normal reaction to jugular compression. Faintly cloudy fluid (20 cc.) was removed, which contained 426 white blood cells per cu. mm. of which approximately 90 per cent were polymorphonuclear, and 10 per cent mononuclear cells. Spinal fluid glucose was 20 mg., chlorides 587 mg., protein .35 gm., per 100 cc., and the Wassermann and colloidal gold reactions were negative in all tubes. A direct smear of the centrifuged fluid stained with Gram's stain demonstrated many small clumps of large Gram-positive cocci. An acid-fast stain of a centrifuged specimen was negative for acid-fast organisms. A pellicle did not form upon incubation of the fluid. Cultures on red blood plates revealed a large Gram-positive coccal organism growing in small colonies.

The clinical impression on admission was that the patient had meningitis, which seemed most likely to be tuberculous. In view of the bacteriological findings, however, the diagnosis of an acute staphlococcal meningitis was later made.

Soon thereafter she became delirious, confused, and unco-operative. She was given penicillin, 200,000 units intramuscularly every two hours, and 200,000 units intravenously twice daily. A lumbar puncture three days later revealed a pressure of 450 mm. fluid, normal dynamics, and a faintly turbid fluid showing 443 cells per cu. mm., approximately 90 per cent of which were polymorphonuclear cells. The staphylococcus was again cultured from this fluid. Intrathecal injections of 10,000 units of penicillin in 10 cc. of saline were then given twice daily. Another lumbar puncture revealed essentially the same findings, with the staphylococcus again being isolated. Penicillin dosage was increased to 500,000 units intramuscularly every two hours and 500,000 units intravenously twice daily on the presumption that the organism isolated was penicillin-resistant.

The temperature ranged between 101 and 103.6 degrees F. during this interval, and a slight clinical improvement was noted with decline of the fever. Roentgenograms of the chest, sinuses and skull were interpreted as normal. Three blood cultures were sterile. Physical findings including neurological examination remained unchanged.

The clinical improvement was short-lived, and she again became disoriented and unco-operative, with a rising fever and urinary retention. Sulfadiazine was then added to the therapy. A spinal fluid cell count was done at the time of each lumbar puncture for instillation of penicillin; these counts varied from 260 per cu. mm. to 564 per cu. mm. The differential counts consistently showed approximately 90 per cent polymorphonuclear leucocytes. The staphylococcus was isolated on culture several times following institution of intrathecal penicillin therapy. Spinal fluid pressures continued to rise to over 650 mm. of fluid. The white blood cell count was 14,150 per cu. mm. with 90 polymorphonuclears, 5 lymphocytes and 5 monocytes per 100 cells on the fifth hospital day. Her general condition continued to deteriorate. The temperature rose progressively and she developed a marked ileus. She showed a variable degree of delirium. Six days after her admission she suddenly went into deep coma, developed Cheyne-Stokes respirations and expired.

Approximately two hours after death, autopsy was performed by the Department of Pathology of Ancker Hospital under supervision of Dr. John Noble, Chief Pathologist. Following is a summary of the significant positive findings.

Autopsy Findings

Abdomen.—Both parietal and visceral peritoneal surfaces were found to be studded with firm yellow nodules from 1 to 10 mm. in diameter. The loops of bowel were firmly adherent to one another with dense adhesions, binding the entire bowel into a single mass. There was a large abscess containing a thick, granular, necrotic, yellow-white material posterior to the uterus. There was no free peritoneal fluid. The appendix was absent.

The tubes and ovaries were bound into a mass by dense adhesions bilaterally. The tubes were enlarged to approximately twice normal diameter. The walls were thickened and the lumina contained a caseous, white material. The corpus of the uterus appeared to be normal, although the cervix was bluish in color and patulous and the entire organ was firmly adherent to the posterior wall of the urinary bladder.

Thorax.—Both lungs were partially adherent to the parietal pleura. There was no free fluid in either pleural cavity. There were a few small, yellow, firm nodules in the pleura medially and in the apex of the pleural cavity on the right. The heart and pericardium were normal.

The right lung weighed 190 gm. On cut section it appeared normal. The left lung weighed 195 gm. It was normally crepitant, and appeared normal on cut section except for a slight increase in blood and fluid in the lower lobe.

Head.—The brain weighed 1,280 gm. There was a fine fibrinous exudate localized largely to the base of the brain and upper end of the cord. The lateral ventricles were enlarged to twice normal size. The brain was of softer consistency than normal, especially over the left temporal area. There were no areas of hemorrhage, infarction, or abscess on cut section.

Microscopic Findings.—There was marked round cell infiltration in all layers of the meninges. The brain showed a marked perivascular infiltration with round cells around the meningeal vessels. The bowel showed areas of caseation and round cell infiltration with typical Langhans giant cells in the bowel wall. The hilar lymph nodes showed areas of caseation, surrounded by epithelioid cells and Langhans giant cells. The lung showed the alveoli to be distended with a pink-staining homogeneous material. Many of the septae were thickened and the capillaries congested. Scattered throughout both lungs were many minute isolated tubercles. Other organs appeared within normal limits.

Final anatomical diagnosis.—Tuberculous meningitis, pulmonary tuberculosis, tuberculous peritonitis.

Several weeks following autopsy of this patient, the guinea pigs which had been innoculated with the spinal fluid on admission were sacrificed and examined and typical tuberculous lesions were demonstrated.

Comment.—Several unusual features of this case are of interest. The clinical picture presented by the patient when first seen during the final phase of her illness strongly suggested tuberculous meningitis, and this diagnosis was tentatively made. This was strengthened by the strong probability that the pelvic infection was tuberculous in etiology, in spite of the negative chest roentgenographic findings and a negative Mantoux reaction. The repeated presence of a Gram-positive coccus with cultural characteristics and appearance of a staphylococcus in the spinal fluid was thus an unexpected finding. This led to the erroneous impression that the staphylococcus was solely responsible for the meningitis in spite of the spinal fluid cell count which was certainly unusual in a meningitis due to an organism of the coccal group.

The route by which either of these organisms gained access to the meninges is not clear. A ruptured tuberculoma was not demonstrated although the brain was carefully sectioned with this in mind. The spinal cord was not examined at autopsy and the possibility remains that a small ruptured tuberculoma existed here. There were no neurological findings suggestive of a cord lesion however. There was neither clinical nor roentgenographic evidence of tuberculous osteomyelitis of the spine. The time relation between the extraction of the infected teeth and the onset of symptoms of meningitis suggests that bacteremia following this extraction might have resulted in infection of the meninges with the staphylococcus. The unusual degree of resistance of this organism to penicillin both clinically and *in vitro* further suggests that it may have been related to the dental infection and that it was present at the time when she received the prolonged courses of penicillin. The antibiotic resistance of the organism may well have been enhanced in this fashion.

The staphylococcus was studied in detail by Dr. Ellard Yow of the Bacteriology Laboratory of the Department of Medicine, University of Minnesota Medical School. Antibiotic sensitivity studies were carried out. The organism was not inhibited by 78 units per ml. of penicillin and 10 micrograms per ml. of streptomycin. These levels are well beyond the levels usually attained clinically and justify the conclusion that the organism was relatively resistant to these substances. It was sensitive *in vitro* to aureomycin.

The reason for the minimal cellular reaction observed in the spinal fluid of this patient is also not clear. Riley noted in his case and in several others reported, in which one of the organisms present was Mycobacterium tuberculosis, that the polymorphonuclear exudate usually found in infections with a pyogenic organism, was replaced by a lymphocytic reaction with relatively low total spinal fluid cell counts. Several possible explanations of this phenomenon might be entertained. In the present case, the low spinal fluid cell response and lack of typical purulent meningeal involvement at autopsy might be related to some alteration in the staphylococcus by previous prolonged exposure to penicillin and sulfonamide drug. More likely, however, is the possibility that the presence of tuberculous involvement of the meninges in some way changed the response of these tissues to a usually pyogenic organism and thus changed the character of the exudate. The cases noted by Riley which showed this phenomenon apparently did not involve organisms that were resistant to antibiotics.

A low white blood cell count is also unusual in the presence of a meningitis caused by a pyogenic organism. This finding is further evidence of an altered relationship between the invading organism and the host.

As noted previously, this is apparently the first reported case, at least since 1911, in which Mycobacterium tuberculosis and a staphylococcus were isolated. Of the cases collected by Riley, all were tuberculous combined with some other organism. In twenty-three cases, the other infecting organism was the meningococcus; four were combined with the pneumococcus, two with Friedlander's bacillus, one with an unidentified organism growing in tetrads, and two with unidentified organisms. Several points worthy of repetition here are stressed in Riley's review. Since dual infection does not produce a distinctive clinical picture, the diagnosis of this condition can be made only by appropriate bacteriological methods. Failure of the patient to respond to currently available therapy of the suppurative meningitides may be an important clue suggesting the presence of two invading organisms. In the case reported here, lack of response was of little value in the light of the known high resistance of the organism to penicillin.

All cases reported, save that of Riley and the present case, were reported prior to 1944; i.e., before the time when streptomycin was freely available. Apparently there are no cases reported thus far in which therapy with streptomycin has been attempted. All cases have been fatal. It would seem that if the tubercle bacillus could be demonstrated microscopically in the spinal fluid of such cases, or if extremely suggestive clinical findings point to a dual infection, a course of both intrathecal and intramuscular streptomycin following accepted dosage schedules for tuberculous meningitis[2,3] might be indicated after appropriate cultures and animal inoculations for isolation of the tubercle bacillus have been obtained. Admittedly, the ultimate salvage rate in tuberculous meningitis alone is low, approximately 20 per cent,[1,3] but it would seem that this offers the sole hope of cure in these patients at present.

Summary

1. A case of meningitis with two infecting organisms has been reported. The patient had simultaneous infection with Mycobacterium

(Continued on Page 429)

CHILDHOOD MORTALITY FROM ACCIDENTS

A. B. ROSENFIELD, M.D., M.P.H.
Minneapolis, Minnesota

ACCIDENTS are the leading cause of death in children over one year of age. Between the ages of one and nineteen years, accidental fatalities in Minnesota during 1951 constituted 38.5 per cent of the 826 deaths in that age group (Fig. 1). Accidental deaths in this age group almost equalled the total of the deaths due to malignant neoplasms, congenital malformations, diseases of the central nervous system, pneumonia, influenza, poliomyelitis, heart disease, and rheumatic fever. Accidents were responsible for three times as many deaths (318) as were caused by all communicable diseases (106). As a matter of fact, accidents are the leading cause of death up to age thirty-five, beyond which heart disease, cancer, and intracranial vascular lesions, the degenerative diseases of old age, take the lead.

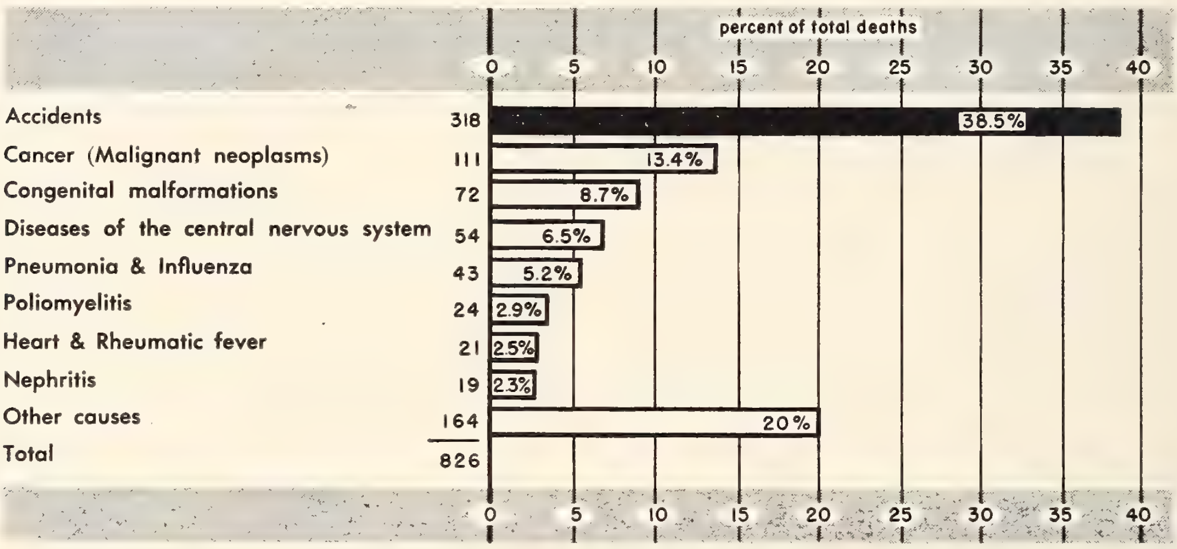

Fig. 1. Deaths from selected causes, ages one to nineteen years, by occurrence in Minnesota, 1951 (Provisional).

In 1900, tuberculosis was the leading cause of death in Minnesota and the United States. It was known as the "Captain of the Men of Death." Pneumonia took a high toll at all ages. Communicable diseases were responsible for a high mortality, particularly during childhood. Accidents were the fourth leading cause of death. Half a century later, in 1951, tuberculosis had dropped out of the ten leading causes of death in Minnesota. It has been in eleventh place for the past three years. Deaths due to pneumonia have decreased 75 per cent. Communicable diseases are rarely responsible for death during childhood. But accidents, the fourth leading cause of death in 1900, are today still in fourth place. Reduction of deaths from disease in recent years has been twice as great as reduction in deaths from accidents. As a result, accidents are now responsible for more deaths than any other cause in childhood, except during infancy.

TABLE I. SUMMARY OF ACCIDENTAL DEATHS OCCURRING IN MINNESOTA IN 1951
(Provisional)

Type of Accident	All Ages	Per Cent	0–19 Years	20–44 Years	45–64 Years	65 Years and Over
Grand Total	1,804	100.0	366	442	354	642
Occupational	171	9.5	12	64	66	29
Home	601	33.3	131	35	54	381
Motor Vehicle	653	36.2	131	247	155	120
Public	359	19.9	91	93	77	98
Late effects*	20	1.1	1	3	2	14

*Deaths due to accident but occurring more than one year after the accident.

Accidental Deaths in Minnesota

For all ages, a total of 1,804 accidental deaths occurred in Minnesota in 1951, an increase of 5 per cent over the 1950 total of 1,712 deaths.

Dr. Rosenfield is Director, Division of Maternal and Child Health, Minnesota Department of Health.

While the 1951 statistics are provisional, it is expected that the final figures will not cause any significant changes. The National Safety Council estimated a nationwide increase of 4 per cent for 1951.

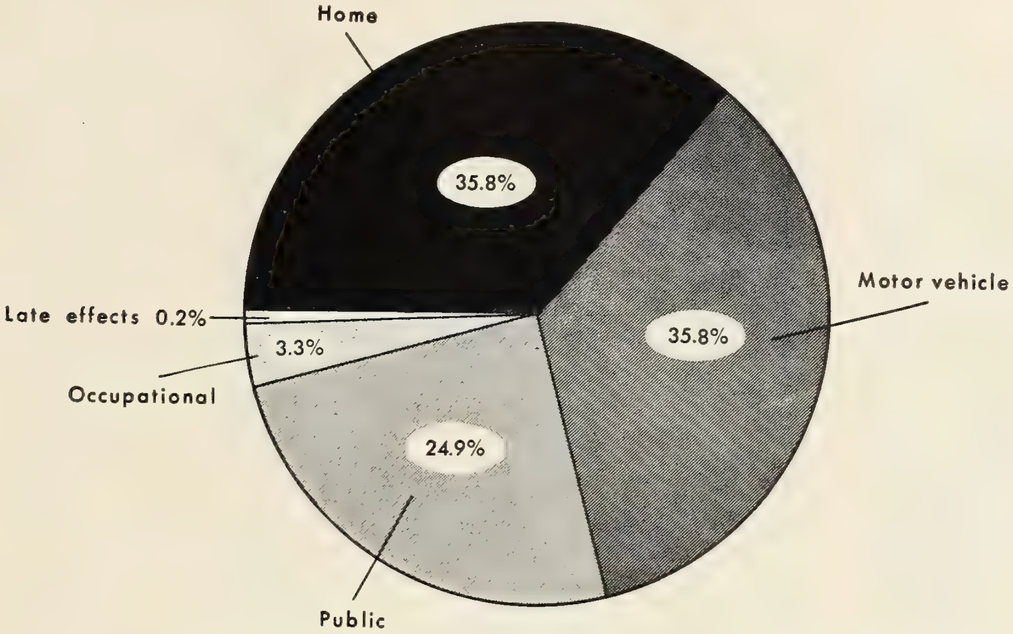

Fig. 2. Accidental deaths by major classification, by percentage during childhood (infancy to nineteen years), by occurrence in Minnesota, 1951 (Provisional).

TABLE II. PRINCIPAL CAUSES OF ACCIDENTAL DEATHS IN CHILDHOOD OCCURRING IN MINNESOTA, 1951
(Provisional)

Type of Accident	Total Under Age 20		Under One Year		1–4 Years		5–9 Years		10–14 Years		15–19 Years	
	No.	%	No.	%	No.	%	No.	%	No.	%	No.	%
Total	366	100.0	48	100.0	96	100.0	65	100.0	62	100.0	95	100.0

Accident from machinery	10	2.7	—	—	—	—	—	—	3	4.8	7	7.4
Accident from electric current	4	1.1	—	—	—	—	—	—	2	3.2	2	2.1
Other	37	10.1	4	8.3	13	13.6	4	6.1	9	14.5	7	7.4

Home accidents constituted one-third of all accidental deaths (601 deaths), a decrease of 5 per cent from 1950 (Table I). Motor vehicle accidents caused slightly more than one-third of the deaths (36.2 per cent) and increased 3 per cent over 1950. Public accidents, other than motor vehicle, were responsible for one-fifth of the deaths, and occupational accidents caused one-tenth, an increase of 1 per cent over 1950. Twenty per cent of all accidental deaths occurred in persons under the age of twenty years, 24 per cent in those between twenty and forty-four years, 20 per cent between forty-five and sixty-four years, and 36 per cent in persons sixty-five and over.

Fatal Accidents During Childhood (0-19 Years)

Of the 366 accidental deaths during childhood (under age twenty), 131 (36 per cent) were home accidents, and a similar number were motor vehicle fatalities. Almost three-fourths of the accidental deaths in childhood were therefore due to home and motor vehicle accidents and one-fourth were due to public accidents (Fig. 2).

Turning to the principal causes of accidental death in childhood, motor vehicle accidents were in first place for the age group infancy to nineteen years, with 36 per cent of the deaths. Motor vehicle deaths exceeded all other types of accidents for the specific age groups one to four years, five to nine years, ten to fourteen years, and fifteen to nineteen years. The only exception was during infancy, under age one (Table II). Drownings were in second place with 18 per cent, burns in third place with 10 per cent, and firearm fatalities in fourth place with 5 per cent. In fifth place was mechanical suffocation; sixth, falls; seventh, poisoning; and eighth, obstruction, suffocation, or puncture by ingested objects.

There were definite sex differences, with 73 per cent of the accidental deaths occurring in males. Motor vehicle fatalities, drownings, burns, firearms and machinery accidents occurred preponderantly in males. These are shown graphically in Figure 3.

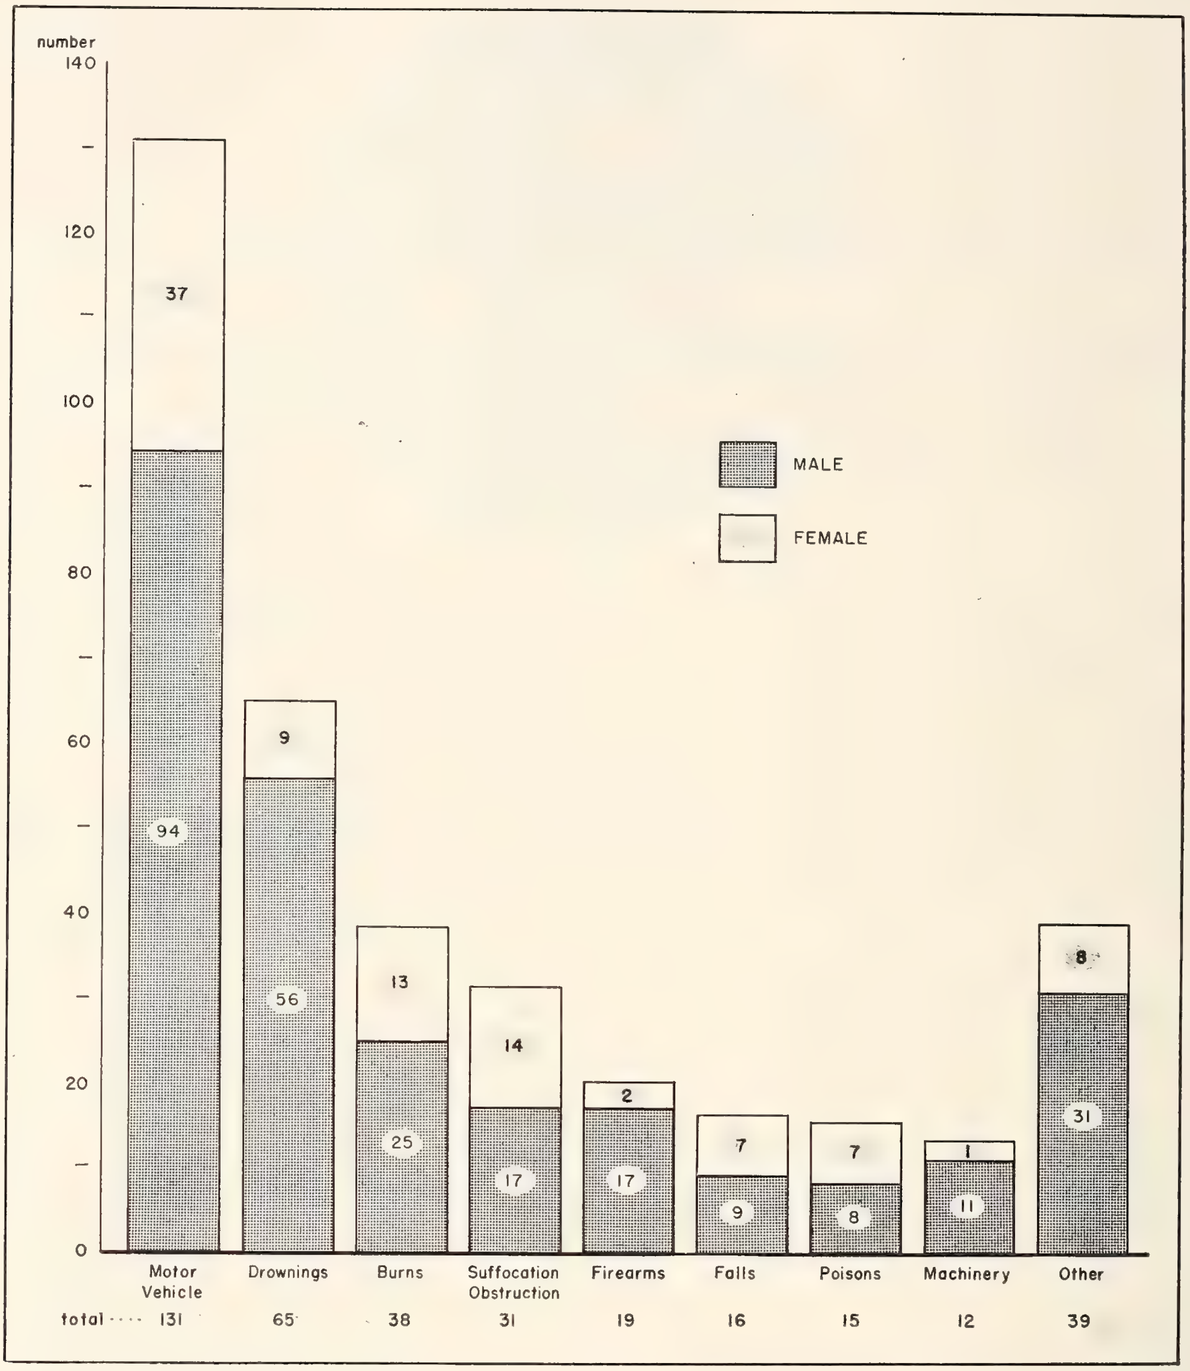

Fig. 3. Major causes of fatal accidents in childhood (infancy to nineteen years) by sex, by occurrence in Minnesota, 1951 (Provisional).

Fatal Accidents in Infancy

During infancy (the first year of life) there were forty-eight accidental deaths (Table II). While this number is small in comparison with the total number of infant deaths (1,918) and constituted only 2.5 per cent of the infant deaths, it is important to note that there has been a 60 per cent decrease in infant deaths from all causes since 1915, but only a 10 per cent decrease in deaths due to accidents. More than one-third of the accidental deaths in infants were due to mechanical suffocation in bed or cradle (Fig. 4). While fourteen of these deaths were coroner's cases, only one autopsy was reported. The total of seventeen such deaths is only one less than the number reported in 1950, in spite of continued emphasis that such deaths are for the most part actually the result of an acute respiratory infection and require adequate autopsies for diagnosis. Obstruction, suffocation, or puncture by inhaled or ingested objects were in second place, responsible for almost one-fifth of the deaths. Motor vehicle accidents and falls were each responsible for 10 per cent of the deaths, followed by burns and poisoning. One eleven-months-old infant ran into a river and was drowned.

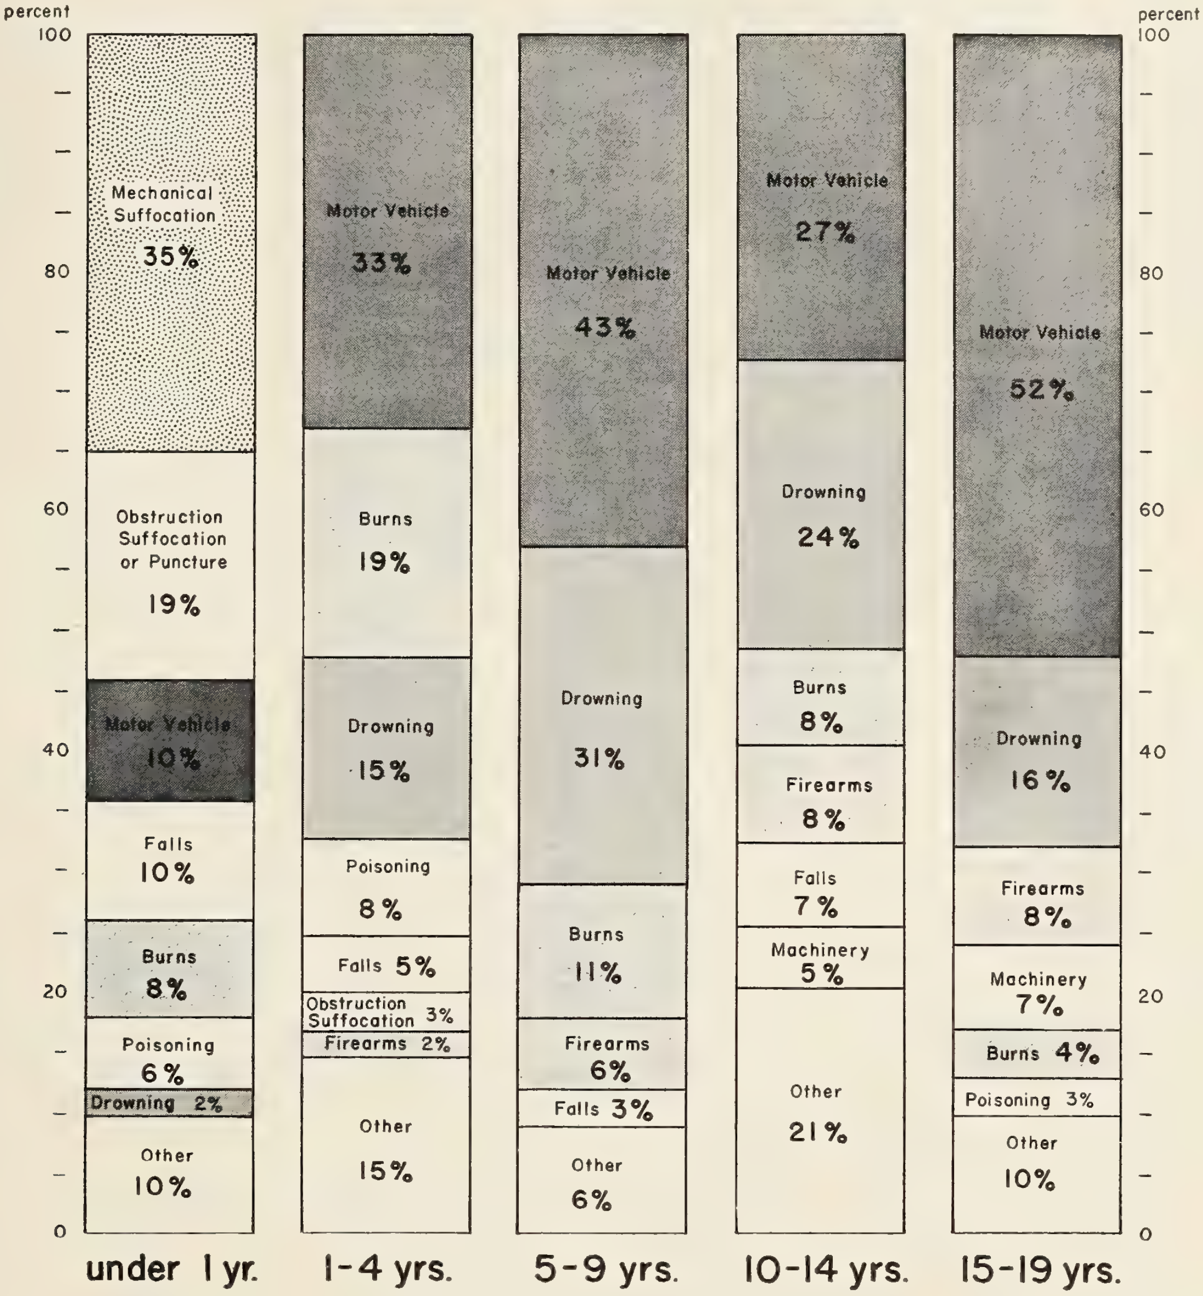

Fig. 4. Principal causes of fatal accidents in childhood. Per cent distribution for selected age groups, by occurrence in Minnesota, 1951 (Provisional).

Fatal Accidents in the Preschool Age Child

In 1951, for the preschool child (one to five years of age), accidental deaths constituted 30 per cent of all deaths, with a total of ninety-six such deaths (Table III). There were more deaths due to accidents than the total of all the deaths due to cancer, pneumonia, influenza, and all other communicable diseases. Almost twice as many deaths were due to accidents (ninety-six) as were due to pneumonia and influenza (twenty-five) and all other communicable diseases (twenty-five).

7. Nephritis		4	2.9
All other causes		17	12.1

Considering the principal causes of accidental deaths, there was a marked difference between the rank order for the preschool child and for the infant (Fig. 4). The first and second leading causes of accidental death in infancy—mechanical suffocation and obstruction or suffocation from ingested objects—almost disappeared in the older age group. The lead was taken by motor vehicle accidents which accounted for thirty-two deaths—one-third of the total (Table II). In second place were burns, with almost one-fifth of the deaths (eighteen). In third place was drowning, with 15 per cent (fourteen deaths), followed by poisoning with 8 per cent (eight deaths) and falls with 5 per cent (five deaths).

Fatal Accidents in the Younger School Age Child

In children between the ages of five and nine years, accidents accounted for sixty-five deaths (37 per cent of all the deaths) (Table IV). There were more accident fatalities than the total of all the deaths due to cancer, congenital malformations, poliomyelitis, pneumonia and influenza, tuberculosis, diphtheria, measles, and whooping cough. There were more than twice as many deaths caused by accidents as were caused by all communicable diseases.

As the leading cause of accidental death, motor vehicle accidents increased to 43 per cent (twenty-eight deaths) in the child from five to ten years old (Table II). Drowning was in second place, with more than one-fourth of the deaths (eighteen deaths). In third place were burns, responsible for 11 per cent (seven deaths), followed by fire arms with four deaths and falls with two deaths (Fig. 4).

Fatal Accidents in the Older School Age Child

Between the ages of ten and fourteen years, accidents were the leading cause of death, constituting 44 per cent of the deaths with sixty-two accidental deaths out of a total of 140 deaths (Table V). There were as many accidental fatalities as the total of the next seven leading causes of death, and four times as many as the deaths from all communicable diseases including pneumonia and influenza.

Considering the principal causes of fatal accidents, it can be seen from Table II that motor vehicle accidents continued in the first place in the older school child with more than one-fourth of the deaths (seventeen), closely followed by drownings with fifteen deaths. In descending order were burns with five deaths, firearms, five, and falls, four (Fig. 4).

TABLE VI. DEATHS FROM SELECTED CAUSES, AGES FIFTEEN TO NINETEEN YEARS, OCCURRING IN MINNESOTA, 1951

6. Congenital malformations		9	4.6
7. Nephritis		6	3.0
8. Suicide		6	3.0
All other causes		27	13.8

Fatal Accidents During Adolescence

Between the ages of fifteen and nineteen years, ninety-five deaths or almost one-half of all the deaths were due to accidents (48 per cent). In contrast, deaths from cancer, rheumatic fever, heart disease, diseases of the central nervous system, congenital malformations, and all communicable diseases constituted only 30 per cent of the deaths in this age period (Table VI).

Motor vehicle accidents constituted more than one-half of all the accidental deaths between fifteen and nineteen years of age, a total of forty-nine deaths (51.6 per cent) (Table II). Drownings were in second place with fifteen deaths. Firearms rose in this age group to third place, with eight deaths, followed by deaths due to machinery with seven deaths, and burns with four (Fig. 4).

Summary

A total of 1,804 accidental deaths occurred in Minnesota in 1951. Twenty per cent of these fatalities occurred in persons under the age of twenty years. Between the ages of one and nineteen years, accidental deaths constituted 38.5 per cent of all the deaths in this age group and almost equalled the deaths due to cancer, congenital malformations, diseases of the central nervous system, pneumonia and influenza, poliomyelitis, heart diseases and rheumatic fever. Three-fourths of the accidental deaths occurred in males.

The leading cause of accidental death during childhood (infancy to nineteen years) was motor vehicle fatalities, responsible for 36 per cent of all accidental deaths. In second place, drownings were responsible for 18 per cent of the deaths. In third place were burns with 10 per cent. In fourth place were fatalities due to firearms. During infancy, under the age of one year, mechanical suffocation was the leading cause of accidental death, with obstruction, suffocation, or puncture due to ingested objects in second place.

The majority of deaths from accident are considered preventable and constitute a serious public health problem. Many of these deaths can be prevented by increased public attention to the problem, by education of parents regarding safety at home and at work, by proper education of children in safety by the home and the school, by close supervision of children at play, by sanitary engineering, by better control of water and traffic hazards, and by enforcement of necessary regulations.

MENINGITIS

(Continued from Page 423)

tuberculosis and a staphylococcus that showed high *in vitro* resistance to penicillin and streptomycin.

2. It is suggested that in meningeal infections from which a pyogenic organism is isolated, where initial spinal fluid cell counts are low, where a spinal fluid lymphocytosis is present, where the patient has a known tuberculous infection, or where response to therapy is poor, appropriate bacteriological procedures for the immediate demonstration and cultural isolation of tubercle bacilli from the spinal fluid should be undertaken.

3. The treatment of these cases with the currently accepted regime of streptomycin for tuberculous meningitis is suggested.

A TRANSFUSION PROGRAM FOR RURAL HOSPITALS

G. A. MATSON, Ph.D., and R. W. KOUCKY, M.D.
Minneapolis, Minnesota

EVERY LABORATORY worker can readily understand that in some respects laboratory problems in small outlying hospitals are much different from those in the larger urban hospitals. The lesser volume of laboratory work in the small hospital results in some procedures being done only occasionally with long lapses of time often occurring between tests. Therefore the technologists' experience with such procedures is necessarily limited. Pathologists and special laboratory workers are not immediately available and interpretation of laboratory findings and the resultant decisions as to therapy or procedure must be made by the attending physician without assistance.

These problems in laboratory work are particularly apparent on the transfusion services of small hospitals. Within the past ten years only, there has developed in this field a tremendous complexity of technical procedures. Former techniques employed in matching bloods for A-B-O and Rh compatabilities are no longer satisfactory. Furthermore, the technologist is expected to be conversant with sensitization phenomena and to be familiar with the methods of detecting such sensitizations. Cross-matching problems resulting from cold agglutinins, high serum viscosity, artifacts as well as from subgroup sensitization are often difficult even for the technologist working exclusively with transfusion problems. These difficulties are correspondingly greater in the small hospital laboratory.

Notwithstanding recent advancements in knowledge and improvement of laboratory methods, transfusion reactions occur too often. From our experience it appears that more deaths result from hemolytic transfusion reactions than from appendectomies. It has become clear, therefore, that in a transfusion service the long-felt need for safer transfusions can and should receive first consideration. To accomplish this in a small rural hospital, it is necessary for laboratory personnel to be given the opportunity to go periodically to some reliable center to receive refresher training in the newer methods of cross-matching and handling blood and to compare notes on procedures. The technologist should acquaint herself with the workers in this special field so that she can call, write or otherwise consult with them whenever difficult problems confront her. The technologist in the small hospital must in this way be provided with competent, expert help in the confusing situations which periodically confront every transfusion worker.

The next most important part of a transfusion program is procurement of blood for major emergencies. The two situations which make up the majority of these emergencies necessitating immediate use of large amounts of blood are obstetrical accidents and gastrointestinal hemorrhages. The following case illustrates the situation very well: Recently, in a Minneapolis hospital, a young mother underwent an apparently normal delivery. She was returned to her room at about 4 p.m. Hemorrhage developed, however, and the patient was given 17 pints of blood before midnight of that day. Unquestionably, this young woman would have died if that blood had not been continuously available. That type of emergency can arise at any time in any hospital irrespective of its size. Every reliable transfusion service must be capable of handling such emergencies.

It is basically unsound in Minnesota to attempt to supply from a distance the complete transfusion needs of a small rural hospital. In Minneapolis, blood is delivered from a certain bank to participating hospitals. The distance to any one of these hospitals is not more than five miles. Nevertheless, in order that blood can be delivered promptly in emergencies, it has been found necessary to equip the blood bank delivery truck with a telephone, red lights and a siren. The Minneapolis War Memorial Blood Bank would not undertake to cover emergency situations reliably in outlying hospitals even at distances no

---

Although the Minneapolis War Memorial Blood Bank is the official blood bank of the Hennepin County Medical Society, its services have not been denied to physicians and medical groups in outlying towns and counties when specific requests for these services have been made through proper channels. This paper will be sent to physicians in rural towns as a reply to inquiries concerning supplementary blood bank service which the Minneapolis War Memorial Blood Bank can offer.

Mr. Matson is Director and Dr. Koucky is Medical Executive of the Minneapolis War Memorial Blood Bank.

farther than 20 to 30 miles. It was found, in fact, that last winter and spring during the period of heavy snows, there was difficulty in delivering blood for ordinary routine work. It is our opinion that reliable emergency coverage can be attained only if the outlying hospital organizes a program whereby blood for emergency can be immediately available from within the local community. Such programs must be accepted as a community need similar to volunteer fire departments. In implementing a rural emergency transfusion program, it must not be overlooked that quarters, equipment, supplies and above all, personnel experienced in drawing blood from donors must be in readiness at all times. The daily drawing of blood for routine use is the best assurance that the physical equipment and technical skill will be available when an emergency arises. The "know how" must remain with the hospital laboratory. Furthermore, the community should have available an adequate supply of plasma to supplement its emergency blood program. Physicians, firemen, highway patrols, sheriffs, ambulances, hospitals, and all key points should all be supplied with plasma. Every obstetrical delivery room should keep plasma within the room. Plasma should be stocked throughout the community so that it is immediately available to control emergency situations until whole blood can be used.

Procurement of blood for the ordinary routine transfusion needs is seldom a problem. In small communities there is a close association between the hospital, the physicians and the citizens which makes easy the procurement of blood. But it is somewhat difficult to know how much blood should be kept continuously on hand. There should be enough so that the ordinary minor emergencies due to an unexpected need for two or three units of blood can be handled by the bank without calling upon the community volunteers. Numerous public calls for blood for emergencies of minor degree may dull the community response and enthusiasm. Experience indicates that a hospital should maintain about one unit of blood for each five or six beds. This, of course, varies considerably with the type of medical practice in the particular hospital. It seems advisable that such an inventory should be uniformly maintained.

Since the use of blood is unpredictable, however, there could result a significant waste due to outdating. Any waste of blood is undesirable. To eliminate this waste, the small blood bank should arrange with an urban central bank for an outlet for units of blood which might otherwise become outdated.

Exchange of bloods between banks is not, however, a simple matter, particularly if the central bank is government licensed. In such blood banks the Department of Biologics Control of the National Institutes of Health rigidly regulates the movements of the blood bank's biologic products. It is important that procedures such as the selection of donors, the preparation of the skin, the type of equipment, the storage and handling of the blood all follow definitely prescribed standards. The central bank in order to accept units of blood must instruct, supervise, and control the techniques and personnel of the affiliating bank. Such instruction and supervision should be part of the plan even though it were not required by the NIH, since it is part of a general education program so much needed in transfusion work throughout the country.

Acceptable units of blood sent to the central blood bank are credited, unit for unit received, to the local bank. This credit is used to provide the plasma needed by the community. It can also be used to provide unusual or special bloods not available in the local bank. Finally, this credit is used to provide blood for members of the community requiring transfusions away from home. In Minnesota, patients are frequently referred by their physician to other institutions such as the University, Veterans Hospitals, or Twin City private hospitals, and to various clinics. The central blood bank acts as a clearing house and arranges for an exchange of credits. In this way it is possible for citizens of a community to donate blood in their own home town for relatives or friends hospitalized in these various institutions or even in hospitals as far away as Seattle, San Francisco or Miami.

The requirements of a sound, reliable transfusion program for small outlying hospitals can be summarized as follows:

1. Association with a large central blood bank to which the technologist can go to learn the newer approved technical procedures, and to which she can turn for help with her problems.
2. Organization of a local self-sufficient system whereby blood for emergency may be immediately available at all times.

3. A local supply of plasma available at all key points in the community.

4. A reasonable inventory of whole blood to cover daily uses and ordinary minor emergencies.

5. An outlet for units of blood which are becoming outdated.

6. A source for special blood not available in the local bank.

7. An affiliation with a central clearing house for blood, permitting exchange of credits between institutions.

8. An affiliation with a central blood bank laboratory offering consultancy assistance in the study and analysis of difficult transfusion problems, transfusion reactions, Rh antibody titrations, Coombs test, genetics studies, and other problems dealing with hereditary antigenic factors in human blood.

How can all of these requirements be satisfied within one program? We have been changing the details of our plan from time to time so it is obvious that a final perfect program has not been devised. We do feel, however, that our basic pattern is workable and useful.

It is our recommendation that the local physicians, the hospital and lay groups organize a campaign to acquaint the people of the community with the requirements of a reliable transfusion program and with the details of the proposed project. We suggest that leading civic groups take over this project and maintain it year after year under the supervision of the physicians. In some communities this civic group consists of a committee which has a representative from each of the various organizations of the community.

Volunteer blood donors to start and maintain a blood bank are solicited. These volunteers are of two types. Volunteers coming from farms and towns away from the location of the hospital make up one group. From this group, donors may be called at about 10-day intervals. Out of the entire group which sometimes numbers several hundred, only a few are drawn at a time—only enough to maintain the blood bank inventory at the desired daily level. Each person who deposits blood in the bank establishes a credit which entitles him and his dependents to receive blood as needed. Unused credits should be canceled at some predetermined interval, perhaps at two years, in order to facilitate bookkeeping and keep the bank solvent.

The second group of volunteers, those living in the town in which the hospital is located, are all typed, indexed and organized into an emergency group, members of which will immediately come to the hospital at any time when called. This group may also be called upon for nonemergency needs. Individuals having certain types of blood are called by the laboratory technologist as needed to maintain proper type distribution of blood in the bank. This second group of volunteers are all given credit in the blood bank as soon as the group is organized. They can then withdraw blood even though the individual member has not yet been called to make a deposit.

It has been found that the great majority of people in the community do not establish any credit in the bank. When persons from this group receive a blood transfusion a deposit of $35.00 must be made for each unit used, to encourage the patient to have his friends and relatives replace to the bank unit for unit the amount of blood which has been used. Failing to do this, the $35.00 is forfeited and goes into the blood bank fund. Irradiated liquid plasma used from the bank is replaced by blood in the same way.

In the case of rural hospital blood banks affiliated with the Minneapolis War Memorial Blood Bank, the technologist responsible for the management of the rural blood bank must come to the Minneapolis War Memorial Blood Bank and work with its personnel for not less than one week. It is required that she continue under the supervision of the central bank after she returns to the hospital blood bank and that she be placed on the payroll of the Minneapolis War Memorial Blood Bank to emphasize its control over her. Her salary from the central bank is, to say the least, not large. It is important that this technologist be kept informed of all new methods employed by the central bank, and it is especially desirable that she calls upon the central bank for help with any problems.

As units of blood in the rural hospital blood bank become seven to ten days old, they are sent to the Minneapolis War Memorial Blood Bank, while at the hospital replacements are made from either the volunteer group or from patients' relatives. The local blood bank is credited with all bloods arriving in good condition at the Minneapolis War Memorial Blood Bank.

Currently, an adequate reserve of plasma is on hand at the Minneapolis War Memorial Blood Bank to permit loaning to the local bank as many units of plasma as are needed—twenty to thirty is the usual number. This loan of plasma is paid off as time goes on from the whole bloods sent to the Minneapolis bank. It is customary to ask two units of blood for each 250 cc. unit of plasma—one unit to provide the plasma itself, and a second unit to cover the cost of processing, filtration and radiation.

The blood sent to the Minneapolis Bank also builds up the credit out of which can be provided blood at the various institutions to which patients might be referred. Blood can also be replaced at the Minneapolis War Memorial Blood Bank for that already used at other institutions. If blood is actually transported to these institutions, for example to the Mayo Clinic, a shipping charge is made to the patient receiving the blood. In all cases there is, of course, a service charge for the laboratory work done on these bloods. In the Twin City area the total charge covering both the Minneapolis Blood Bank's work and the Hospital laboratory work ranges from $12.00 to $16.00. The Minneapolis War Memorial Blood Bank's part of this fee is $6.00.

If the local technologist has difficulty in selecting a suitable blood for a transfusion, she may send a blood sample from the patient to the Minneapolis Bank for selection of a compatible blood from our larger stock. Such bloods also are provided from the hospital's credit at the central bank.

Unused credits at the Minneapolis War Memorial Blood Bank are canceled at the end of a year, but this is done at monthly intervals so that the hospital always has available the past twelve months of unused credits.

Unquestionably, this plan will require further modification. It is, however, already apparent that as our experience has increased, our ability to help other blood banks has improved. The program has been found to materially strengthen and support the laboratories and blood bank service of the affiliated rural hospitals, large or small. It is a plan which does not supplant but rather supplements the activity of the rural hospital blood bank and keeps the "know-how" of bleeding donors and other blood bank and laboratory procedures in the hospital. Yet, due to the backing which is offered by the central bank, by supplementing the hospital's own supply of blood in emergencies, by supplying rare types of blood when needed, by supplying selected blood for use in difficult transfusion problems, by giving laboratory assistance in the study and analysis of difficult transfusion problems, by laboratory assistance in case of transfusion reactions, by training laboratory personnel from rural hospitals in approved techniques of modern blood bank work, by extended supervision of blood bank techniques in rural hospitals, and by dissemination of scientific information to physicians, nurses, technologists, etc., by means of reprints, pamphlets and by direct correspondence, the physicians, hospitals and community enjoy a transfusion security and safety which is invaluable.

Based on our experience, we can say with confidence, even now, that this basic pattern is working and that it can ultimately develop into a dependable state-wide system of blood banking.

PSYCHIATRIC IMPLICATIONS OF THE ATOMIC AGE

(Continued from Page 408)

fense against the atomic bomb. It has come to be the accepted fact among people, that some day the atomic bomb is going to drop, and so a state of constant fear has been developed, together with a state of general insecurity and confusion and uncertainty, which, combined, have produced in a great many of our people a feeling of indifference. They have become resigned to the inevitable. They no longer can think for themselves in terms of the past when there was no such threat in existence. A spirit of "let's live while we can and get all we can out of it" has developed. People have become to be more or less fatalistic in their attitude. They have come to expect the inevitable and with a shrug of the shoulders they turn to today in order to live as best they can without plans for the future. This, then, is the psychiatric implication of the Atomic Age.

President's Letter

SELF DISCIPLINE—PUBLIC SERVICE

In fostering accessibility to medical care facilities, services and information, the medical profession has developed an all-important safety valve for doctor-public relationships: county medical society grievance committees.

There is much that the public does not understand about the principles and practice of medicine; and the tensions of illness often contribute to these misapprehensions. Unchecked, a single misunderstanding may grow and multiply into a full-scale community antagonism against the medical profession.

I use the word "misunderstanding" to describe the unpleasant situations that can arise between doctor and patient, because in all but a small percentage of cases, the physician's failure to serve his patient has not been a professional failure, but an omission in explanation, in providing the patient with a fundamental grasp of the factors involved in his condition, the procedures of treatment, and methods of financing medical or surgical care.

When the patient comes away from his doctor's office, bewildered, perhaps a little frightened by the unknowns of his ailment, and apprehensive regarding the financial aftermath, he is well on his way toward becoming a public relations problem.

Fortunately, most physicians have become actively aware of their responsibilities in health education and the number of misunderstandings between patients and physicians is dwindling, as a result. However, the grievance committee network throughout the county medical societies is an ever-ready safeguard against the consequences of neglected public relations problems.

The public is served by the profession's facilities for self-discipline in two ways: first, any real case of negligence or unethical conduct on the part of the physician is promptly dealt with by his medical society; and second, a clearer understanding of the medical principles involved is always achieved.

Self-discipline and a conscientious approach to the problems that concern both the profession and the public are noteworthy among American medicine's contributions to standards of American medical care.

PHYSICAL DIAGNOSIS—A LOST ART?

AUSTIN FLINT, in 1862, speaking of physical diagnosis, remarked that "so large a part of the profession bestow little or no attention on the subject." What would his impressions be if he were to return today?

The multiplicity of diagnostic aids available today has had the tendency to lessen the time and effort spent at the bedside, and many physicians are neglecting to obtain and apply all the information available from the simple methods of physical diagnosis. In fact, many doctors have not been adequately taught and have not troubled to perfect themselves in carrying out the physical examination. Too little time is allotted for the instruction of the undergraduate in the important field of physical exploration of the patient, and the tutelage is often relegated to the less experienced members of the staff. Later then, in the urgencies of practice the doctor is quite apt to gloss over or omit part of the examination, assuming that the x-ray or the laboratory will provide him with all the answers.

The physical methods of examination, inspection, palpation, percussion, and auscultation require no extraordinary acuity of the senses, but do require a knowledge of anatomy, physiology, and pathology, together with a good technique practiced with painstaking care. A systematic approach and thoroughness are requisite. A hurried, casual, or partial examination is almost no examination. Some teachers emphasize one of the methods particularly. Full use should be made of all.

"The trouble with most doctors isn't that they don't know enough as it is that they don't see enough."—Corrigan.

Diagnostic acumen often attributed to cleverness really consists of long and diligent experience in the exercise of observation. Many of the older clinicians testify to the value of inspection, and the keenness of their observations is reflected in the descriptions of what they saw. In the intervening years no one has improved upon the word picture of the irregular respiration as written by Dr. Cheyne and Dr. Stokes. Some of the world's great masterpieces in oil and sculpture depict readily recognizable medical conditions even though the artist may have been unaware of their significance. Palpation is of inestimable value in some situations. Percussion and auscultation may signify little or nothing if one listens but does not hear. In 1951, a great clinician felt impelled to publish a monograph on proper auscultation of the heart.

It is necessary to know, not only what the methods are capable of demonstrating, but also to know and recognize their limitations, and what should not be expected of them. Micrometer accuracy cannot be achieved with a yardstick, but properly used the yardstick may be a useful and valuable instrument. Often the student does not become fully aware of the fact that morbid physical signs are not directly diagnostic of particular disease, but are related to and significant of the physical conditions produced by the disease.

A pain in some general location of the body is often sufficient to occasion the reference to the roentgenologist, and the report then becomes a diagnosis with a minimum of cerebral or physical activity on the part of the clinician.

Such approach does not permit proper selection of the procedures required. Too much or too little is done. The thoughtless accumulation of tests (the exactness of which may be more apparent than real) does not actually constitute what is commonly referred to as a "work-up." In fact all too commonly only further confusion may result, and it is unfair to the roentgenologist and the pathologist, to ask or expect them to do the clinician's job.

It is only after a thorough clinical study that intelligent requests for special procedures can be made. Furthermore, proper correlation of the various studies can only be achieved in connection with the entire clinical picture.

"We do not lack in appreciation of the revolutionary discoveries of Laennec, nor do we regard his labors as in any way inferior to the chemical and physiological studies now being so assiduously pursued."—Hamman.

Mechanized diagnosis is leading to the loss of the charm and joy of approaching an individual rather than "a case." The senses are becoming impaired by disuse atrophy. The human side of medicine always has been, is now, and ever will be the prime consideration of the good physician.

Especially today with such widespread interest in the high cost of medical care, it is incumbent upon every practitioner to listen to the patient (he may be telling you the diagnosis), and carefully conduct a thorough physical examination.

Then care and some degree of wisdom may be used in selecting the necessary special studies requisite to the welfare of the patient. In this way, we can make further effort in the fulfillment of our obligations as physicians.

T.A.P.

NEW ANTI-TUBERCULOSIS DRUGS

THE STRIKING RESULTS obtained by the use of derivatives of isonicotinic acid in the treatment of clinical tuberculosis which was reported in the January, 1952 issue of the *Quarterly Bulletin of the Sea View Hospital* at Staten Island were not long in being brought to public notice. Three New York newspapers carried articles on February 21, and from there on the news spread like wildfire. The search for specific medication for diseases, including tuberculosis, has been going on for years. From time to time one is added to the medical armamentarium, and now it seems very likely that one has been found highly effective in the treatment of tuberculosis. While it is a little premature to give an accurate and final evaluation of the value of the new drug, enough patients have been treated successfully to warrant real optimism.

The drug known as isonicotinic acid hydrazide was first synthesized by two chemists in Austria in 1912. It was synthesized again independently by Dr. H. H. Fox of Hoffmann-LaRoche, Inc., Nutley, New Jersey, in 1942 and more recently by a team of chemists of E. R. Squibb and Sons, New Brunswick, New Jersey. Its chemotherapeutic activity was discovered independently by the research staffs of the two companies. Rimifon® was the name given the drug by Hoffmann-LaRoche and Nydrazid® by Squibb. Its isopropyl derivative is known as Marsilid®.

Both Rimifon® and Marsilid® were tested as to their anti-tuberculosis effectiveness against test tube cultures and by oral and subcutaneous administration to infected mice and monkeys. Their action seemed to be bactericidal rather than bacteriostatic. When they were found to be more effective than streptomycin, P-aminosalicyclic acid,- or any of the other tuberculostatic drugs they were tested out in small doses last summer on five severely ill tuberculous patients at Sea View Hospital. Beginning last fall, some ninety-two patients at Sea View Hospital were treated with larger doses, and it was originally planned to report the results of a six months' trial in April. The results were so startingly successful that the staff evidently could not refrain from making the preliminary reports in the hospital's *Quarterly Bulletin* for January. While some undesirable side effects, such as sore arms, vertigo, constipation and hyperreflexia were reported, there was no evidence of any organ damage and the effects on the tuberculous infection, both pulmonary and extrapulmonary, were so favorable and at times even dramatic that large supplies of the drugs have been made available and have been supplied to sanatoria all over the country for experimental use. The drug is not yet available for private use.

If widespread use confirms the preliminary reports, Rimifom® and Marsilid® will contribute a great adjunct in the treatment of a disease which still takes its toll of thousands yearly.

COMMISSION ON FINANCING OF HOSPITAL CARE

THE INVESTMENT in hospitals in this country amounts to billions of dollars and duplication of present facilities at present-day costs would require two or three times the original investment. The cost of hospital care is placed at several billion dollars yearly and has skyrocketed in recent years. The many factors including inflation, high wages, high taxes and fewer large donations have made the going rough for many hospitals. It is important that the necessary steps be taken to maintain the services of the hospitals within the reach of the general public directly or through insurance.

A commission of thirty-three members, each one chosen for the contribution he was considered able to make to the operation of the commission, has been established to investigate all phases of the hospital problem and is sponsored by the American Hospital Association. A fund of $500,000 has been created by the Health Information Foundation, Milbank Memorial Fund, National Foundation for Infantile Paralysis, Rockefeller Foundation, W. K. Kellogg Foundation and John Hancock Mutual Life Insurance Company to finance the study. Two years will be taken to complete the investigation.

The report of the Commission will be awaited by the public and the profession with interest. It is to be hoped that valuable recommendations will be made.

The following article by Dr. Howard A. Rusk, an associate editor of the *New York Times* and a member of the Commission, is informative.

HIGH QUALITY HOSPITAL CARE AT LEAST COST BEING SOUGHT

Citizens' Group Studies Institutions' Rising Expenses in New Service to Public

By Howard A. Rusk, M.D.

When the Pennsylvania Hospital was organized in 1751 through the efforts of Benjamin Franklin and Dr. Thomas Bond as the first voluntary hospital in the United States, its founders, as is done today, appealed to the public for funds. But, unlike today, the £2,750 raised were found to be more than were actually needed.

From this high point 200 years ago the situation of American hospitals has steadily grown worse until today most voluntary hospitals face severe financial problems.

In comparison to their modest beginnings, American hospitals have grown to be big business. Last year the 6,430 hospitals in the United States had a total valuation of $7,791,000,000; equal to $52 for each individual in the nation. The cost of care for the 17,023,513 patients they admitted to their 1,456,912 beds totaled $3,650,000,000.

As compared to $1.19 in 1900, the average daily cost for one patient in the nation's 4,713 general hospitals was $15.62 last year. This increase has resulted not only from the general increase in the price of all commodities, services and wages, but stems from the fact that hospitals today render services unheard of fifty years ago. This increased cost has been partly offset, for the individual patient's hospital stay has been materially reduced. In 1900 the average hospital stay was thirty-two days; in 1950 it was 8.1 days.

This fact, however, is academic to the individual who faces a large hospital bill. He is concerned that hospitals now take an increasing percentage of each dollar he spends for medical care. Last week's issue of *The Journal of the American Medical Association* reports that as compared to 14 cents in 1930 and 17 cents from 1935 to 1940, hospitals last year took 23 cents of each dollar spent for medical care. Of the $8,500,000,000 spent for medical care in 1950, $2,400,000,000 went to physicians, $2,000,000,000 to hospitals, $1,400,000,000 for drugs and sundries, and $1,000,000,000 to dentists.

Group Seeks Improvement

With these and other similarly disturbing facts to be faced, a citizens' committee of thirty leaders from all walks of American life, meeting in Washington recently, announced a two-year action program aimed at "providing high quality hospital care at the lowest possible cost to the public." The group, known as the Commission on Financing Hospital Care, is headed by Gordon Gray, president of the University of North Carolina and former Secretary of the Army. It is financed by grants from philanthropic foundations, voluntary agencies, businesses and individuals, and will report directly to the public.

The commission's first project will be a state-wide pilot study of hospital financing in North Carolina, starting in January. North Carolina was chosen for the study as the necessary information on costs is already available there. From previous studies done there the commission hopes to develop recommendations that will have nation-wide application in solving the problems connected with paying for hospital care.

In direct contrast to Europe, where most hospitals are owned and operated by governments with funds raised primarily by taxes, about 75 per cent of the income of the non-governmental hospitals in the United States is received from patients' fees. Although substantial funds are regularly contributed to non-profit, voluntary hospitals for new buildings, additions and repairs, few hospitals have endowment funds of significant size for operating expenses. In 1935 the endowment income of non-profit hospitals was a little less than 6 per cent of the total income.

Charitable giving to hospitals has not kept pace with rising hospital costs. Further complicating the problem is the fact that most local and state governments still pay far less than the actual hospital costs for services given medically indigent patients. For example, the cost of ward care in New York City voluntary hospitals is from $15 to $20 a day, but the city has only $11 for such care.

Private Patients Hardest Hit

As a result, private patients, particularly those who have not been covered by prepayment insurance, have been hardest hit as their personal resources have been easiest to tap. As these self-paying patients provide most of the operating income for the maintenance of voluntary hospitals, the ability of this class of patient to pay complete hospital charges undoubtedly will be a major consideration in the commission's studies.

Another factor the commission will consider is the effect of hospitalization insurance on hospital financing. It is estimated that at the end of last year 76,961,000 persons in this country had one or more insurance policies to defray the cost of hospital care in full or in part. In 1949 the insurance benefits of these policies amounted to $530,000,000 and paid for 26 per cent of all consumer expenditures for general hospital care. Of this amount, $303,000,000 in benefit payments were by hospital-sponsored Blue Cross, $192,000,000 by commercial companies, and $35,000,000 from independent plans.

There is little doubt that hospital care is an indispensable service that organized society must maintain. If the present system of financing and distributing health services in hospitals needs modification, the decision for change must be based on facts. Since little recently collected data is available for study, the new Commission on Financing of Hospital Care should provide a valuable service in determining how we may provide "high quality hospital care at the lowest cost to the public." The consumer will eagerly await the answer.—*New York Times,* December 9, 1951.

TODAY'S HEALTH

If *Today's Health* were to be found on the reception-room table of every doctor's office, it would mean that the reliable medical information which it contains would have a more widespread dissemination. If, too, *Today's Health* were recommended by each doctor to his patients, the value of this lay medical journal would be further enhanced. The increased subscription which would follow both these actions would eliminate the deficit occurring each year in its publication which is met by the publishers, the AMA, the physicians of the country. *Today's Health,* formerly *Hygeia,* is a valuable medium for transmitting reliable medical information to the public. It is our baby and should not be neglected.

AMA MEETING—JUNE 9-13

The proximity of Chicago as the place of meeting of the American Medical Association in June should appeal to members of the Minnesota State Medical Association. The JAMA of April 12, 1952 contains in detail the program for the meeting.

The progress of scientific medicine in recent years has been outstanding. In no field of medicine has progress been greater than in the field of therapeutics. A visitor to the AMA convention in June will have a mass of scientific material from which to choose, and he cannot fail to add interesting and valuable material to his fund of knowledge.

The scientific meetings will be held at Navy Pier for the most part. The House of Delegates will meet at the Palmer House. Members are welcome to attend the meetings of the House of Delegates and its reference committees and to learn how the affairs of the Association of which he is a member are conducted.

For the information of those who will remain at home, two television broadcasts of convention activities will be carried over the NBC television network and will be sponsored by Smith, Kline and French Laboratories in co-operation with the AMA. This is the first time such a broadcast will have been attempted.

AMERICAN HEARING SOCIETY

Founded in 1919 by the late Wendell C. Phillips, M.D., the American Hearing Society, 817 14th St. N.W., Washington, D. C., is a nonprofit, social service organization devoting its efforts to prevent deafness, conserve hearing and rehabilitate the hard of hearing. Affiliated with the Society are 115 chapters from Maine to California. A chapter offers some or all of the following services: lipreading instruction, hearing tests and hearing aid consultation, classes for preschool hard of hearing youngsters and their parents, speech correction, auditory training, employment guidance and recreational programs.

WHICH WAY AMERICA?

I am grateful for this opportunity to talk to you as a physician working for the present in political life.

Doctors today have to be political economists as well as diagnosticians. The practice of our profession has changed because of circumstances outside the medical profession. It becomes not only wise, it becomes imperative for us to pay a great deal more attention to government because government today reaches into everybody's life every hour of every day. Whether we will long have the chance to use with success and satisfaction the scientific knowledge and skills we have worked so long to acquire will be determined by how well we handle our political affairs.

What happens in the world depends more than anything else on what the United States of America does. Her economic strength and political influence are still so great, her productive capacity, her military capacity and her moral strength are still so great that which way the United States goes is likely to be decisive in determining which way the whole world goes. Which way the United States goes depends upon what philosophy of government we choose, and the kind of people we choose to carry out the basic tenets of that philosophy.

Nobody needs to be apologetic about talking politically today. Conceivably we could solve all our medical problems and have better care more adequately distributed; we could solve our housing and education problems, our old age security and labor-management problems, our highways and bridges and airport problems, and all the other things we are properly interested in and concerned with.

But unless we manage our political relations with the rest of the world better than we have—and unless we end too frequent and exhausting wars or mobilization for defense, none of those domestic gains can endure.

And unless we handle our political problems better here at home so that we have better government, there is no gain, medical, social, or otherwise that is long going to be worth much to anybody.

Political Responsibility of Physican-Citizens

So we have to approach our times not only as physicians but as citizens. What we know as medical people must and should influence our conduct, our attitudes, and our activities as citizens. And our obligations as citizens must influence our conduct as medical people.

It isn't because we are doctors that we oppose the quack socialistic medical programs proposed here and there. It is because as doctors we know what will happen to medical care under such systems. Doctors themselves would by and large be better off—as long as there was anybody left able to pay the bills. It's the public that would be worse off. I don't need to enlarge on that.

England tried to get security for her people by turning everything over to the government. They put so much on it that the government is now insecure. How

---

Address delivered by Honorable Walter H. Judd, M.D., Minnesota Representative, before the Eighth Annual Conference Woman's Auxiliary to the American Medical Association, Chicago, Illinois, November 15, 1951.

much security do they have? None—unless we hold them up. The doctors opposed it, not because they were trying to get something for themselves, but because they saw what was going to happen to medical care in a country following that sort of idea.

Lewis Douglas, our ambassador to Great Britain said, "After watching the socialistic experiment in Britain, I concluded that only a rich country can afford socialism, and only the poor ones are foolish enough to adopt it."

That was a wise comment. The people didn't see what they were going to lose—the doctors did. That's why they had to oppose it. The people thought they were going to get more and better medical care for less. Doctors knew they would get less and poorer medical care for more. The doctors under that system were going to be so busy taking care of those who needed it least, or only thought they needed it, that they would be prevented from giving good care to those who needed it most. We warned the British about it the best we could, but they went through with it anyway. I hope we will learn from their sad experience, and not have to learn from our own.

Forefathers' Philosophy Built Most Productive Nation

May I examine for a moment the history of what has developed here in this country—not just where we are, but why.

Some 330 years ago, our forefathers came to this continent. What for? To get a government to provide for them? No. That's what they had where they came from. They came here to get a chance to try to provide for themselves.

As a result of that philosophy in their hearts and of their political concepts, they built a society which released as had never been done before in any time, in any place, the creative capacities that are in ordinary people everywhere. There took place here the greatest outburst of creative effort, imagination, energy, production and progress that the world has ever seen. It rushed ahead to the point where today the seven per cent of the people of the world who live in these United States have created as much wealth and have distributed it more widely than all the other ninety-three per cent put together.

Why did that happen? Because of some good fortune or chance? No.

Was it because we had superior ability as compared with the other ninety-three per cent? Of course not.

Was it because we had greater resources? No. Theirs in total are greater than ours.

The basic reason was an economic system based primarily on the right of the individual—and opportunity for him to get ahead. That's what young people especially want—a chance to get ahead.

What the world needs is not our wealth, but the secret of our wealth. Wealth comes from only one thing—production of goods and services. Therefore, what the rest of the world needs is the secret of our production. How can they get their own countries on a more productive basis? They have to discover and apply the political and economic philosophy which brought our forefathers here some 330 years ago.

Europe Needs U. S. Production System

Last summer in England an Englishman said, "We are always over there trying to get your goods. But it's not so much your goods we need; what we really need is your system. In Europe the system is to try to get rich by making as few things as possible at as high a price as possible. In America the system is to try to get rich by making as many things as possible at as low a price as possible."

The biggest problem of ECA today—the one thing it hasn't succeeded in getting over is that for them to take our goods which are the result of the productive process here, is not enough. They must be willing to adjust their thinking and adapt their economic and political systems to take also the secret of our production. They can produce the same as we can here, if they will change their concepts.

In essence, the struggle throughout the world today and in our own country is a struggle between two philosophies of government—between those who believe in government from above down and those who believe in government from the bottom up. Put another way: it's a struggle between those who put their primary faith and reliance in a few experts, supposed supermen government executives, and so forth, at the top; as against those who put their primary reliance and faith in the good sense and capabilities of ordinary people, if genuinely free.

Our people came here to get away from systems where one man ruled, or one party ruled, or one race ruled, or one class like the aristocracy ruled, or one particular sect ruled, and the final decision was in the hands of the few. They came here to build a system where the final decision would be in the hands of the many.

Another way to say it is that it is a struggle between the only two basic forms of government there have ever been—dictatorship and federation. I use those terms rather than totalitarianism and democracy, because the latter have been so abused that they no longer mean the same things to different people. A dictatorship exists when any man or group or bloc, even if it be a majority, imposes its will without any reservation of rights for the opposition, or the minority. A federation exists when people establish a mechanism whereby some group or party can come to power and govern; but certain rights are reserved for the opposition, including the right to try to become the governing group. One is based on compulsion, the other is voluntary. The people decide the manner in which they are to be governed and they, not the government, decide what powers it is to have.

The year 1776 was the birthday not only of the United States, but of political liberty throughout the world. Up to that time governments had controlled people. This was the first time people set up a constitution by which they could control government.

Do We Govern Ourselves?

A lot of people think that in our system people govern themselves. The President in his July Fourth speech said that we must demonstrate to the Soviet

Union and the world "that people can govern themselves." The fact is that people have never been able to govern themselves directly, and I don't think they can now. Our forefathers debated that system and rejected it. We don't govern ourselves. Rather, we choose the government, which means we choose the mechanism, and the people to operate it.

May I illustrate by a story. Upon going home after my first session in Congress, representatives of one of the big labor organizations called upon me. They were pretty rough and I saw that they had figured out how to give me the third degree. The first man said I was the tool of big business, the banks and corporations. Then he tossed the ball to the next fellow who took me over the coals for allegedly being in the pockets of some other evil group.

When they got through, the cleanup man said, "Mr. Congressman, we have made our views apparent to you. We have 8,000 members in our union here in Minnesota." He dangled them before me, you see. "Each member represents about four votes. That makes 30,000 votes, and elections in this district are determined by ten, twelve, or fourteen thousand majorities. We want to know whether from now on you are going to vote with labor."

I said, "I have never voted with labor and never will. I have never voted against labor, and never will. I vote for or against individual bills on the basis of whether they seem to me to be in the interest of the United States, because only if they are in the interest of the United States can they be in the interest of labor, agriculture, business, the medical profession, or any others in our population.

"This first man said I was in the pockets of big business. Now you ask me to get into the pockets of labor. No, thank you. I am not going to be in anyone's pocket. If I were the sort to get into your pockets, I'd get into the other fellow's pocket if he offered greater inducements. Why don't you want me to be what my title is—*United States* Representative—not just a delegate from the CIO, or the NAM, or the Farm Bureau, or the AMA?"

Balance of Power Is Essence of Government

Some people believe in dictatorship by medicine or agriculture or whatever group they belong to. That's the opposite of our form of government—which is a federation. According to our philosophy, the government's main function is to maintain a just order and a balance—a balance between the branches of government and between the various regions or blocs or interests in the country. That doesn't permit anybody to get everything he wants. But it maintains maximum opportunity and flexibility and equity. These are the heart of the productive process, the secret of our wealth and progress.

So we do not govern ourselves directly, but through representatives whom we choose. Some say to me, "Your mandate is to do so and so." I say, No, my mandate is to govern this country as wisely as I can for the next two years. At the end of the two years you can keep me on or replace me with another representative, depending on whether you think I have governed well or poorly.

It is my political faith that only as my contributions are in the best interests of the United States of America as a whole will they be in the best interest of any group in the country.

Political Evaluation of Medical System

The main thing we need to study is not what happened here, but why it happened. It's like the old philosophical problem of the glass of water that is three-fourths filled. Roughly, three-fourths of the people in the United States have better medical care than anywhere else in the world. The average is higher than elsewhere, but there are some below the average. It is less than twenty-five per cent and it may be because they prefer to spend their money for liquor or some fad or quack remedy that they don't have good medical care. But we'll say there are twenty-five per cent.

We medical people tend to concentrate on the fact that seventy-five per cent of the people have good care. The professional reformers concentrate on the fact that twenty-five per cent don't receive the right kind or grade of medical care. The reformer would say of the glass, "It's no good, because it isn't full." He would throw out the three-fourths and start with nothing! We're inclined to say that the system is all right because the glass isn't empty.

But where we ought to be is between those two—neither the radical who would destroy what we have because it isn't perfect; nor the reactionary who says it's good enough because it's better than anybody else has. What we ought to be, as our forefathers were, is progressive conservatives.

Conserve the things that enabled us to get that seventy-five per cent. Hang on to the secret of that, but at the same time, progress so as to expand the good to eighty-five per cent, then ninety-five per cent, and so on. If we don't, the radicals will come in and take over. This is true of medicine or anything else.

Patient Loses Under Socialized Medicine

In medicine, we know what some of the secrets of success are that must be conserved. One of them is the completely voluntary relationship between the doctor and the patient. It's got to be completely voluntary on the part of the doctor or his heart isn't in it, and it's got to be wholly voluntary on the part of the patient or she isn't going to have confidence in the doctor. When the government is in between it can't be voluntary.

Again, there must be no intermediary. When the patient pays the doctor, the doctor works for the patient. Whenever under other systems the doctor gets paid in part or whole by the government, then little by little he comes to work for the government instead of for the patient. The doctor may be better off, but the patient is worse off.

A third value we must conserve is the incentives which our system provides for the doctor to do his best work and constantly to improve himself. One of these incentives is the chance to make a better living and get ahead financially. If you kill that by regimentation of doctors or patients, most men aren't going to do their best, or work their hardest to improve themselves. Another is professional recognition—the chance to advance to higher standing, to win the respect of one's colleagues and the people of the community. That is a powerful incentive. You kill that under a governmental system where promotions are made by order of seniority —or senility, as we call it in Washington.

What is necessary to get ahead under the bureaucratic system? Only two things. One, or course, is to live long enough so you will be eligible for promotion on the seniority basis. The other is not to have any new ideas. You can't get ahead if you have ideas. If you have a good idea, it makes your superior mad at you— why didn't he think of it first? He'll put you in your place. If you have a bad idea, that reflects on him for having such a dumbbell as a subordinate, and he will block the promotion. So don't try anything new—just conform. That's fatal in our profession, as in anything else.

Do you suppose a government agency would have picked out a half-illiterate garage mechanic to set the world on wheels? Yet that's how it happened. Not because Henry Ford was the only person in the world with the idea, but because of the fortunate circumstance that he lived under an economic and political system which gave him the right to try out whatever dream he had as long as he didn't encroach on the right of others to do the same thing.

Do you suppose a government agency would have picked out a half-deaf telegrapher to light the world? Yet that is how it happened—because of the philosophy in this government and its policies which not only made it possible, but encouraged it and rewarded it.

What Are the Functions of Good Government?

Some social workers because of their preoccupation with those who are inadequate or unfortunate—and that problem exists—become so concerned about saving the unfortunate that they think these are the major concern of a good society. They forget that the key thing is not handouts for the relatively few unfortunates, but providing opportunities for the many to become solvent, because only as the many can become solvent will there be anything much for the unfortunate.

A good government must provide basic minimum needs, food, medical care, clothing and housing for those who for whatever reason cannot provide for themselves. That's one of its functions, but not its first function. Its first function is to provide opportunity for those who, given opportunity, can provide for themselves in order for society to progress and build up something for those who can't provide adequately for themselves. Polio, blindness, injury in war, or some great shock may make it impossible for individuals to take care of themselves. Those are the casualties and government must take good care of them. But that's not its primary function.

The philosophy of our forefathers was the philosophy of the umpire—maintain equal rules for both sides. But it's not the umpire's job to play on one team or the other—or to make sure his favorite wins. It's the job of the boys who play the game. It's the umpire's job to make sure that each side has opportunity to do its utmost as long as it doesn't block the other side's chance to do the same.

In short, our forefathers were politically-minded; they were citizens before lawyers, doctors, farmers, or whatever. They recognized what we have so often forgotten, that we are first of all citizens, taxpayers, fathers and mothers, and trustees of a magnificent heritage.

You remember what our forefathers wrote down as the objectives of their government. First, to protect life. Second, to protect liberty—which means liberty to do anything within the law, no matter how foolish it may seem to others. Nobody is wise or good enough to run other people's lives, no matter how intelligent or high-minded he may be. Life, liberty—and this next one which a lot of people misinterpret as meaning that the government is supposed to guarantee happiness. They aren't able to get happiness and so they demand of their Congressman, "Give me happiness."

But that is not what the Declaration of Independence says. What it says is that men are endowed with certain inalienable rights—that is, they can't be separated from you. And governments are organized among men with the consent of the governed—that is, from the bottom up—to protect these inalienable rights, and among them are "life, liberty, and the pursuit of happiness." Whether you get it or not, the government can't guarantee. You can't guarantee that for your own child. The best you can do is perhaps to advise and stimulate him, try to influence him but he has got to make the decisions himself—either toward or away from happiness. That's all a government can do, too—except to help with the wreckage when, exercising his right to free choice, he loafs or deserts his family, or wastes his substance in riotous living.

I can work my little girl's arithmetic problems for her better than she can for herself. Sometimes I'm tempted to do that because it would be easier to work them than to try to explain them. Besides, she'd like to have me do them—she'd even vote for me if I'd do it. But I don't. It isn't because I don't love her or don't want her to get ahead—it is because I do.

Destructive Influence of Too Much Government

I think it can be stated as a law that whenever a government (or a parent) does for its citizens (or the children) that which they have the capacity to do for themselves, it begins to destroy both the capacity and the will to grow and develop, certainly the incentive.

Woodrow Wilson was a genuine political philosopher and a great student of government. In a speech in New York in 1912 he said that the history of man's struggle for liberty is the history of his struggle to hold down the powers of government. On every occasion citizens must resist expansion of the powers of government. It's an astonishing thing that so many of those who call themselves the followers of Jefferson, Jackson, Cleveland and Wilson, are now insisting that the way to increase liberty is on every occasion to expand the powers of government.

I hear my youngsters talking about their so-called social studies when they come home from high school. The other day I heard them talking about the Bill of Rights. They in company with apparently most people in America have been led to think that the Bill of

Rights, the first ten amendments of the Constitution, consists of a list of things that our government is obligated to do for the citizen. Please read them again. You will find that not one of them is a guarantee that our government must do this or that for the citizen. Every last one of them is a guarantee that our government cannot do this or that to the citizen. That's what "rights" are—what a government cannot do.

They are not guarantees by our government. They are guarantees against our government. For example, the government cannot pass a law establishing a religion, no matter how big a majority it has in Congress. It cannot interfere with your right to speak or publish or assemble or petition. It cannot quarter troops in your home in time of peace. And so on. The government cannot—cannot—cannot. That's what rights are; so that you can do them for yourselves.

It is the particular duty of the legislative branch—every member chosen directly by the people—to hold down the ever-expanding executive branch. Some say the legislative branch is a branch of the government. I think it's truer to say it is, or should be, the branch that is against the government.

In Washington when you call any of the executive departments on the phone the operators say "Government"—and they are right.

Dangerous Emergency of Bureaucratic Law

At the federal level there are 533 officials elected by and therefore responsible to the people; 435 are in the House of Representatives and 96 are in the Senate. That's 531. The other two are the President and the Vice President. The Vice President doesn't count unless the President dies; so you have only one in the Executive Branch elected by the people out of the thousands there who try to run your lives.

The people choose those in the legislative branch, and can unchoose them, on the basis of what they know about them. And they know what they are voting for or against. The people in my district know all about me. They know my education, by background, whether I pay my debts, whether my family is honorable; they know my views and they vote for or against me on the basis of a known quantity.

But did you ever vote for Alger Hiss? No. In fact, did you ever hear of him until he was disclosed as one of the greatest traitors of all times? No man in the legislative branch had as much to do with the foreign policies which lost one war and now have us in another.

Did you ever hear of Klaus Fuchs until you found he had turned the secret of the atomic bomb over to the enemy? You didn't know Hiss' or Fuchs' views or training or attitudes. And of the estimated 200,000 people in the Executive Branch who have power to make policies, only ONE of them ever submitted his credentials to you—the President. He can't possibly know individually more than perhaps 2,000 of those 200,000. To whom are the rest responsible? Well, they were not elected by the people, so they don't feel responsible to the people. They are appointed by appointees who were appointed by appointees, who were in turn appointed by appointees. You have no control or even knowledge of them. That's why the legislative branch, every member of which is responsible to you, has to be against the government, everlastingly seeking to hold down its power.

My friends, this is more fundamental and important to you and your families than talking about the price of your husbands' out-calls. Every bit of the training that your husbands have worked so many years to get and their chance to use their brilliant skill and training, depends on how well they and you and I handle our politics, for politics determines government.

I haven't even gotten to foreign affairs and there isn't time now, but it is the same sort of problem there. Too many decisions were made secretly by a few at the top —decisions which the many would never have approved, and which events have proved disastrous. In World War I, I left college as a pre-medic student and went into the field artillery. When we came back, I thought we had done our job. I took off my uniform and went back to school to get my medical education. It never occurred to me that I had just as great a responsibility as a civilian to build a good society here and a just order in the world as I had had the duty as a loyal American to help overthrow the system the Kaiser was trying to impose.

It wasn't those who died and today sleep in Flanders Field who failed. They did their part of the job. It was we who came home who failed. We didn't fail as soldiers, but as citizens.

However little excuse there was for the failure to get a good peace after World War I, there was no excuse for failure after World War II. Some of us cried our hearts out against making deals with the Kremlin at the expense of loyal allies, such as Poland and China. But we didn't have a chance. Even before the war had been won, the victory had been given away in five conferences by decisions that you and I didn't know about until years later. At Casablanca, Quebec, Teheran, Yalta and Potsdam, a few men on our side, with the finest intentions, but assuming powers no men should have in our form of government, were victims of the guile and the diabolic skill of those on the other side who weren't trying to build the kind of world we were interested in. Now our young men pay in blood and all pay in taxes for their errors in judgment.

Don't Underestimate Strength of Our Philosophy

There are really only two things for us to be afraid of: one is that we may fail to understand or may underestimate the enemy—its worldwide strength, its determination to win, the dangerous inroads which the cancer has already made into the vitals of our own nation and into the thinking of our people without their realizing it. The other is that we may fail to understand or may underestimate ourselves—the strength of our own philosophy and faith.

We can defeat the Russian arms by force of superior arms, but we can't overcome their faith except by a better faith more earnestly and devotedly believed in. Don't underestimate the enemy, but don't underestimate our own strength and the basic soundness of our system, and its attraction and appeal to the oppressed millions of the world.

Communism has never yet helped people out of poverty—never once. It is a fake and a fraud. Our essential system based on the right of the individual to get ahead, is the only one under which any people as a whole has been able to rise to higher standards. Why should we be ashamed—why should we be apologetic—why is it that we are hesitant in presenting to a confused world the only concept, the only system which gives them hope? But our economic system came out of a political philosophy—the right of the individual to do whatever he wanted to as long as he did not interfere with the rights of others to do the same.

Religious Faith is Root of American System

So our progress came from an economic system; that system grew out of a political philosophy. But where did that political philosophy come from? It came from a religious faith—which put first the dignity and worth of individual man as a spiritual being—because he is a son of God.

This is the secret of our progress. We take the progress so for granted that we forget its true source. We have lived so long with these values, which are really the result of centuries of conditioning by the teaching and concepts and principles of the Judeo-Christian religious faith, that we tend to think they are human values, that we possess them because we are human beings and that therefore all human beings accept them, too. Since Stalin and his henchmen are human, then they will respond to given situations as do we. No indeed. Their cruelties are not because they are inhuman, but because they are merely human. Men who haven't been conditioned or mellowed or had their characters developed according to moral teachings are like other animals, predatory. We have no right to equate human with Christian.

Most of us in America seem preoccupied with trying to preserve the material results—which came from the Judeo-Christian concept of the nature of man. But a more fundamental thing is to pay attention to the spiritual causes. We must revitalize and strengthen the spiritual roots out of which came the good fruits.

You say, "What can I do?" You can do what Thomas Jefferson did. You have the same opportunity that Alexander Hamilton had, that Adolph Hitler had. Hitler's was a false and distorted idea, but he did have an idea and passionate dedication to it—look at the evil he produced.

Political Participation—Your Duty

You and I have got to do the same thing with the truth. A Chinese saying describes it: One spreads to ten—ten spreads to a hundred. That is the only way any movement ever won.

All this means you have to get into political parties in order to expand your influence on political affairs. Join up with the party that you think is nearest right on the most important issues. You won't agree with it on everything, any more than you agree on every issue with your club, or your church, or even your husband. But you don't pull out of your club and throw brickbats at it. Rather you try to move it in the direction you think is right. Just so, join up with the party you feel closest to and work in it to select good candidates. That is the first step. The second is to elect them. To do that you have to vote for them yourself. And then persuade others to vote for them. And work to get the lazy or the immobile to the polls.

All good people work for the Red Cross, and Defense Bonds and Civil Defense and the Community Chest—that's "the thing" to do. Why isn't it "the thing" for good people to work in politics when politics is going to determine whether they are going to be able to retain or are going to lose every one of the things you and I believe in and stand for?

In addition, more of you have to be willing to be candidates yourselves and to let your husbands be candidates for public office.

That's tough, I can testify, but no tougher than being a soldier. Why do we expect the latter of good patriotic citizens and not the former? If you don't like your congressman, or mayor, or councilman, don't just write to him—run for the office.

True patriotism and good sense require that the highest grades of people be willing to sacrifice their careers to go into public service just as your sons are called upon to sacrifice their careers to go into the Armed Services.

The Best Thing About America . . .

Only when we do these things—not just discuss them, but act—will there be hope. The greatest and most wonderful thing about our country, which we must preserve at all costs, is the opportunity to change the things that we don't like. Thank God our system is such that if conditions are bad, or don't meet our standards, we can correct them—if we will work in politics. The way to begin is with ideas and principles, get persons and parties committed to them, and then translate them into programs.

EDITOR'S NOTE: The above address was most enthusiastically received by the members of the Woman's Auxiliary to the American Medical Association assembled. In spite of the fact that copies of the address were sent to Auxiliary members, the address is being republished in MINNESOTA MEDICINE for the benefit of our readers.

Medical Economics

of the
Minnesota State Medical Association
George Earl, M.D., Chairman

EWING PROPOSAL UNDER NEW GUISE

Consistency is an easy sacrifice to opportunism for Oscar Ewing, it would seem. His most recent about-face occurred before a hearing of the House Expenditures sub-committee which is studying a bill to create a new department of health. Ewing, who has long been ardently in favor of socialistic government compulsory health insurance, and is still all for it, has now stated that he is not in favor of it.

How does such a thing come about? Mr. Ewing is merely making his proposal for elevating the Federal Security Administrator (himself) to cabinet rank "more attractive." He is not in favor of creating a Department of Health. Ewing testified at this hearing: "The soundest and only feasible way to achieve departmental status for the health functions of the Public Health Service is by elevation of the Federal Security Agency, with all the functions for which it is now responsible, to the status of an executive department." But, after hearing a suggestion of Senator Underwood of Kentucky that Mr. Ewing's proposal could be made more attractive if the Government were to announce "complete disavowal of any aims that lead toward socialized medicine," Mr. Ewing did just that. Apparently, he still does not believe that the Government's compulsory health insurance program would be one that leads toward socialized medicine.

IOWA RESIDENTS OPPOSE SOCIALIZED MEDICINE

No doubt Mr. Ewing would think again about his stand if he took seriously the vigorous opposition in the country to any form of socialistic medicine. A recent report from a congressional district in Iowa shows that 91 per cent of the residents are opposed to socialized medicine. A survey was taken of 39,800 persons, and returns were received from 3,870 of them—normal returns expected from such a questionnaire sampling. The survey was taken in the district of Rep. Thomas E. Martin and shows that "every occupational group included in the survey was overwhelmingly opposed to socialized medicine. Opposition to the idea was voiced by 96.6 per cent of the businessmen, 86 per cent of the laborers, 93 per cent of the white collar workers, 91 per cent of the professionals, 94.8 per cent of the farmers and 90.2 per cent of the remainder. . . ."

MEDICAL EDUCATION UNDERGOES EXPANSION

"The greatest expansion program in the history of medical education, to cost $250,000,000, is now under way in this country," states a recent issue of the *New York Times*. "Almost every college of medicine in the United States is planning to increase its physical facilities."

The *New York Times* recently conducted a survey on medical education through questionnaires sent to the eighty medical colleges and the forty-eight state commissioners of education throughout the nation. The survey states:

> "New laboratories, additional classrooms, modern dormitories and special research clinics are on the drawing board or actually under construction. At present the country maintains seventy-three four-year institutions of medicine, and seven two-year colleges. Commissions or fact-finding committees have been set up in at least ten states to map plans for the development of new medical colleges. Some of the existing two-year schools will be expanded into regular four-year, degree-granting colleges of medicine."

Enrollment Swells

Enrollment figures for medical schools have been increasing steadily. The *New York Times'* survey states, "In the current academic year—1951-52—the medical colleges admitted the largest freshman classes in recent history, a total of 7,381 students. The total enrollment has been growing steadily since the end of World War II.

Now it is slightly above 26,000, compared with 23,000 five years ago."

The survey also reports that a record expansion program is well under way in many medical colleges in the country, with nearly half of the schools now engaged in fund-raising campaigns. To offset the financial problems that are troubling the medical colleges, they are seeking from both public sources and private individuals or foundations approximately $200,000,000. The *Times* reports:

> "Eighty-four per cent of the medical schools reported that they were planning to use this money to expand their physical facilities . . . the medical colleges will spend, within the next few years, $50,000,000 for laboratories, $30,000,000 for classrooms and $20,000,000 for dormitories. Another $100,000,000 is earmarked for research and special projects. In addition, the immediate cost for establishing new medical institutions will run above $50,000,000, making an over-all expansion program of a quarter of a billion dollars. . . .
>
> "To meet the increasing demands for more physicians and medically trained men, at least ten states have taken steps to build new medical schools or expand their two-year basic science schools into four-year institutions . . ."

Quality Jeopardized?

A warning was sounded by certain medical deans, who were queried, that increased enrollment in medical colleges to the point of overcrowding would jeopardize the present high medical standards. One dean warned that "classes of more than 100 may weaken the present high medical standards. Rather than greatly increase the enrollment of existing schools, additional ones should be established. . . ." He explained further:

> "One of the present threats to the quality of medical education stems from the fact that members of state legislatures do not understand this point. There have been several instances in the last few years in which the state government has ordered the medical school of the state university to increase its enrollment without providing additional facilities and budget."

Many medical authorities reported that they felt that the existing enrollment can be increased without lowering the quality, if sufficient funds are obtained to add to the physical plant and increase the faculty. The *Times'* survey also reported that all those who were questioned urged that the high standards in medical education be safeguarded.

OPPOSITION STILL CRIES FOR ACTION

Adding to this vast expansion program for the nation's medical colleges is the National Fund for Medical Education which was originated and fostered by the medical men of the country—the American Medical Association. But amidst all this activity to increase the number of physicians to serve the people, comes a demand that the doctors do something to "provide adequate medical care."

In an article published by *America,* a national Catholic weekly magazine, Stephen P. Ryan reported that a recent conference of Southern Catholic leaders reached its most complete agreement in an "angry demand that medical men take some action or let the Government take it for them." The group also agreed that "medical fees . . . are too high, and there were many references to the failure of physicians to provide adequate medical care at a reasonable cost for the middle-class population of the United States."

The positive actions embodied in these activities of expansion and financial support for medical colleges speak for themselves in answering the negative attitude of the groups decrying the do-nothingness of medical men.

WALTER JUDD DESCRIBES DOCTOR-CITIZEN DUTIES

"Doctors today have to be political economists as well as diagnosticians," Dr. Walter Judd told members of the Woman's Auxiliary to the American Medical Association recently. "The practice of our profession has changed because of circumstances outside the medical profession," he continued. "It becomes not only wise, it becomes imperative for us to pay a great deal more attention to government because government today reaches into everybody's life every hour of every day."

He stated:

> "So we have to approach our times not only as physicians but as citizens. What we know as medical people must and should influence our conduct, our attitudes, and our activities as citizens. And our obligations as citizens must influence our conduct as medical people.
>
> "It isn't because we are doctors that we oppose the quack socialistic medical programs proposed here and there. It is because as doctors we know what will happen to medical care under such systems. . . . It's the public that would be worse off. . . ."

Quotes British Ambassador

Dr. Judd said that England tried to get security for her people by turning everything over to the government, and continued: "They put so much on it that the government is now insecure.

How much security do they have? None—unless we hold them up. The doctors opposed it, not because they were trying to get something for themselves, but because they saw what was going to happen to medical care in a country following that sort of idea."

Congressman Judd quoted our ambassador to Great Britain, Lewis Douglas: "After watching the socialistic experiment in Britain, I concluded that only a rich country can afford socialism, and only the poor ones are foolish enough to adopt it."

Forges Positive Philosophy

Urging his listeners to have faith in the American system of governing and not to underestimate the strength of our philosophy, Dr. Judd warned: "There are really only two things for us to be afraid of: one is that we may fail to understand or may underestimate the enemy—its worldwide strength, its determination to win, the dangerous inroads which the cancer has already made into the vitals of our own nation and into the thinking of our people without their realizing it. The other is that we may fail to understand or may underestimate ourselves—the strength of our own philosophy and faith."

Only by putting forth a better faith and working for it more earnestly and devotedly, he continued, can we hope to overcome our enemy and his faith. In conclusion, Dr. Judd observed:

> "Communism has never yet helped people out of poverty—never once. It is a fake and a fraud. Our essential system based on the right of the individual to get ahead, is the only one under which any people as a whole has been able to rise to higher standards. Why should we be ashamed—why should we be apologetic—why is it that we are hesitant in presenting to a confused world the only concept, the only system which gives them hope? . . . Our economic system came out of a political philosophy—the right of the individual to do whatever he wanted to as long as he did not interfere with the right of others to do the same."

Note: The full text of Dr. Judd's address appears on page 438.

GROWING SOCIALISM?

If it is reasonable for the government to provide "insurance" coverage for all citizens—not on a subsistence basis but at a fairly high standard of living—then why shouldn't the government also have the obligation to build automobiles at subsidized prices for all citizens? In fact, why should it not go into the business of supplying everything that the public uses, with the possible exception of the more frivolous types of products and services, if this principle is sound?—Insurance Economics Surveys, February, 1952.

THE MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

230 Lowry Medical Arts Building
Saint Paul 2, Minnesota

Julian F. DuBois, M.D., Secretary

MINNESOTA LICENSE OF WHITE BEAR LAKE PHYSICIAN REVOKED

In the Matter of the Revocation of the License of Keith D. Larson, M.D.

On February 16, 1952, the Minnesota State Board of Medical Examiners revoked the medical license held by Dr. Keith D. Larson, White Bear Lake, Minnesota. Dr. Larson was first cited on April 26, 1950, to show cause why his license should not be revoked because of immoral, dishonorable and unprofessional conduct as defined by law and as specified in the citation. Dr. Larson was specifically charged with having habitually indulged in the use of drugs and with having purchased excessive amounts of various derivatives of opium. Dr. Larson was also charged with diverting a portion of such narotic drugs to his own use, and with having issued fraudulent prescriptions calling for various derivatives of opium, with the drugs obtained thereby being diverted to Dr. Larson's own use. The citation was returnable on the 12th day of May, 1950, at which time the matter was passed by the Board until the 14th day of July, 1950. On that date Dr. Larson appeared in person before the Board and was represented by legal counsel. The testimony of Walter G. Graben, Seattle, Washington, an agent of the Federal Bureau of Narcotics, was taken before the Board in reference to Dr. Larson's purchase and use of various narcotic drugs.

At the hearing, Dr. Larson testified in his own behalf and admitted that he had been addicted to the use of such drugs. Action on the suspension or revocation of Dr. Larson's license was deferred by the Board and Dr. Larson was permitted to continue in medical practice upon certain conditions. Dr. Larson failed to comply with the conditions upon which he was permitted to continue practice. Dr. Larson was notified by the Medical Board to appear before the Board on several occasions, but he failed to do so. On October 10, 1951, Dr. Larson was notified, in writing, to appear before the Medical Board on November 9, 1951. Nothing was heard from Dr. Larson and he was again notified, on October 27, 1951, of the November meeting of the Board. Dr. Larson did not appear, nor did he comply with the notice given to him by the Board. After the Board had adjourned the November meeting, a letter was received from another physician indicating that Dr. Larson was ill. The Board had passed the case until February 15, 1952, and on December 19, 1951, Dr. Larson was sent a letter advising him to be present at the February meeting of the Board. Dr. Larson failed to appear.

Dr. Larson was born at Clintonville, Wisconsin, on April 27, 1914. He received his Doctor of Medicine Degree from Northwestern University on December 3, 1941. He was licensed in Minnesota by examination on May 7, 1943.

Minnesota State Medical Association Roster for 1952

Officers

R. L. J. Kennedy, M.D.	*President*	Rochester
A. E. Brown, M.D.	*First Vice President*	Rochester
Herbert Boysen, M.D.	*Second Vice President*	Madelia
B. B. Souster, M.D.	*Secretary*	Saint Paul
W. H. Condit, M.D.	*Treasurer*	Minneapolis
C. G. Sheppard, M.D.	*Speaker, House of Delegates*	Hutchinson
Haddon M. Carryer, M.D.	*Vice Speaker*	Rochester
R. R. Rosell	*Executive Secretary*	Saint Paul

Councilors

(Terms expire December 31 of year indicated)

First District	John M. Waugh, M.D. (1953)	Rochester
Second District	R. C. Hunt, Sr., M.D. (1953)	Fairmont
Third District	L. G. Smith, M.D. (1952)	Montevideo
Fourth District	H. J. Nilson, M.D. (1954)	North Mankato
Fifth District	Justus Ohage, M.D. (1952)	Saint Paul
Sixth District	O. J. Campbell, M.D. (1954) *(Chairman)*	Minneapolis
Seventh District	W. W. Will, M.D. (1952)	Bertha
Eighth District	C. L. Oppegaard, M.D. (1954)	Crookston
Ninth District	A. O. Swenson, M.D. (1953)	Duluth

House of Delegates, American Medical Association

(Terms expire December 31 of year indicated)

Members

J. Arnold Bargen, M.D. (1952)	Rochester
O. J. Campbell, M.D. (1953)	Minneapolis
George Earl, M.D. (1953)	Saint Paul
F. J. Elias, M.D. (1952)	Duluth

Alternates

Julian F. DuBois, Sr., M.D. (1952)	Sauk Centre
W. W. Will, M.D. (1953)	Bertha
E. M. Hammes, Sr., M.D. (1953)	Saint Paul
Paul C. Leck, M.D. (1952)	Austin

Scientific Committees

COMMITTEE ON SCIENTIFIC ASSEMBLY

R. L. J. Kennedy, M.D., *General Chairman*	Rochester
J. F. Norman, M.D.	Crookston
R. R. Rosell	Saint Paul

Section on Medicine

W. E. Herrell, M.D., *Chairman*	Rochester
P. G. Boman, M.D., *Secretary*	Duluth

Section on Specialties

C. L. Oppegaard, M.D., *Chairman*	Crookston
F. L. Schade, M.D., *Secretary*	Worthington

Section on Surgery

W. P. Ritchie, M.D., *Chairman*	Saint Paul
L. C. Culligan, M.D., *Secretary*	Minneapolis

Local Arrangements

Charles E. Merkert, M.D., *Chairman*	Minneapolis

COMMITTEE ON ANESTHESIOLOGY

R. C. Adams, M.D.	Rochester
J. W. Baird, M.D.	Minneapolis
J. H. Crowley, M.D.	Saint Paul
R. T. Knight, M.D.	Minneapolis

NAPT COMMONWEALTH AND EMPIRE HEALTH AND TUBERCULOSIS CONFERENCE

Arrangements are going ahead rapidly for the Third Commonwealth and Empire Health and Tuberculosis Conference organized by the National Association for the Prevention of Tuberculosis, which is being held in London from July 8 to 13, 1952, inclusive. This Conference is the third to be held since the war by the NAPT, which for over fifty years has been in the forefront of the campaign for the control of tuberculosis. The Association has been privileged in having the patronage of Royalty throughout its existence. King Edward VII was its founder and first President, King George V and King George VI were Patrons, the Prince of Wales (later King Edward VIII) was President, and the late Duke of Kent also President. Her Royal Highness the Duchess of Kent, who succeeded her husband as President, attended both the post-war Conferences, in 1947 and 1949.

The Conference is open to all interested in preventive medicine, including the medical and veterinary professions, commercial and industrial executives, nurses, social workers, health administrators, members of public authorities, regional hospital boards, et cetera. Representatives from twenty-eight countries have indicated their intention of attending. The countries concerned are Argentina, Australia, Belgium, Bolivia, Brazil, Canada, Denmark, Eire, Fiji, France, Germany, Gold Coast, Hong Kong, India, Japan, Jugoslavia, Libya, Mauritius, New Zealand, Nigeria, Northern Rhodesia, Nyasaland, Singapore, South Africa, Spain, Tanganyika, Trinidad, United States of America.

The Minister of Health (Rt. Hon. H. F. C. Crookshank, MP) has promised to attend on the morning of Wednesday, July 9, when Prevention and Care Work by Local Health Authorities, and Protective Vaccination, will be discussed. The Secretary of State for the Colonies (Rt. Hon. Oliver Lyttelton, DSO, MC, MP) will be present at the session on Tuberculosis in British Colonial Territories on Thursday, July 10, and the Secretary of State for Scotland (Rt. Hon. James Stuart, MVO, MC, MP) at the session on Tuberculosis —A Problem for All Peoples on Tuesday, July 8. Other interesting discussions will be on The Social Worker and the Tuberculous Family, The Patient in Industry, and Non-Respiratory Tuberculosis.

Among those who have already promised to speak are: Dr. I. L. Briggs (Northern Rhodesia), Dr. G. C. Brink (Department of Health, Ontario, Canada), Dr. V. Clausen (Vordingborg Sanatorium, Denmark), Dr. F. van Diense (Chief, BCG Department, Institut Pasteur, Paris), Dr. P. W. Dill-Russell (Nyasaland), Dr. Charles Hill, MP (Parliamentary Secretary, Ministry of Food), Dr. J. B. McDougall, CBE (World Health Organization), Dame Dehra Parker (Minister of Health, Northern Ireland) and Dr. John A. Scott (Medical Officer of Health, London County Council).

A new feature of the Conference will be special smaller gatherings for those with particular interests, whether doctors, nurses, public health officials or social workers, at which appropriate subjects will be discussed. There will be a large exhibition of medical and scientific interest, including art and occupational therapy sections and a mass radiography unit in action. Receptions for delegates are being held at many well-known institutions, and a large number of visits to hospitals and sanatoria have been arranged, in addition to tours of general interest.

All information can be obtained from the NAPT, Tavistock House North, Tavistock Square, London, W.C.1.

STATE AND COUNTY TUBERCULOSIS ASSOCIATION

The Minnesota Tuberculosis and Health Association is the new name adopted in February of this year by the Minnesota Public Health Association. It was considered that the new title better indicates the nature of the association's activity and better differentiates it from the Minnesota Health Department with which it has been frequently confused.

The Minnesota Tuberculosis and Health Association began as the Minnesota Association for the Prevention and Relief of Tuberculosis and was founded in 1906. It was also known as the Minnesota Anti-Tuberculosis Association and by 1909 employed a full-time secretary.

It was in 1914 that the Minnesota Association for the Prevention and Relief of Tuberculosis changed its name to the Minnesota Public Health Association, it being felt that the latter name better indicated the wider field of the association's activities.

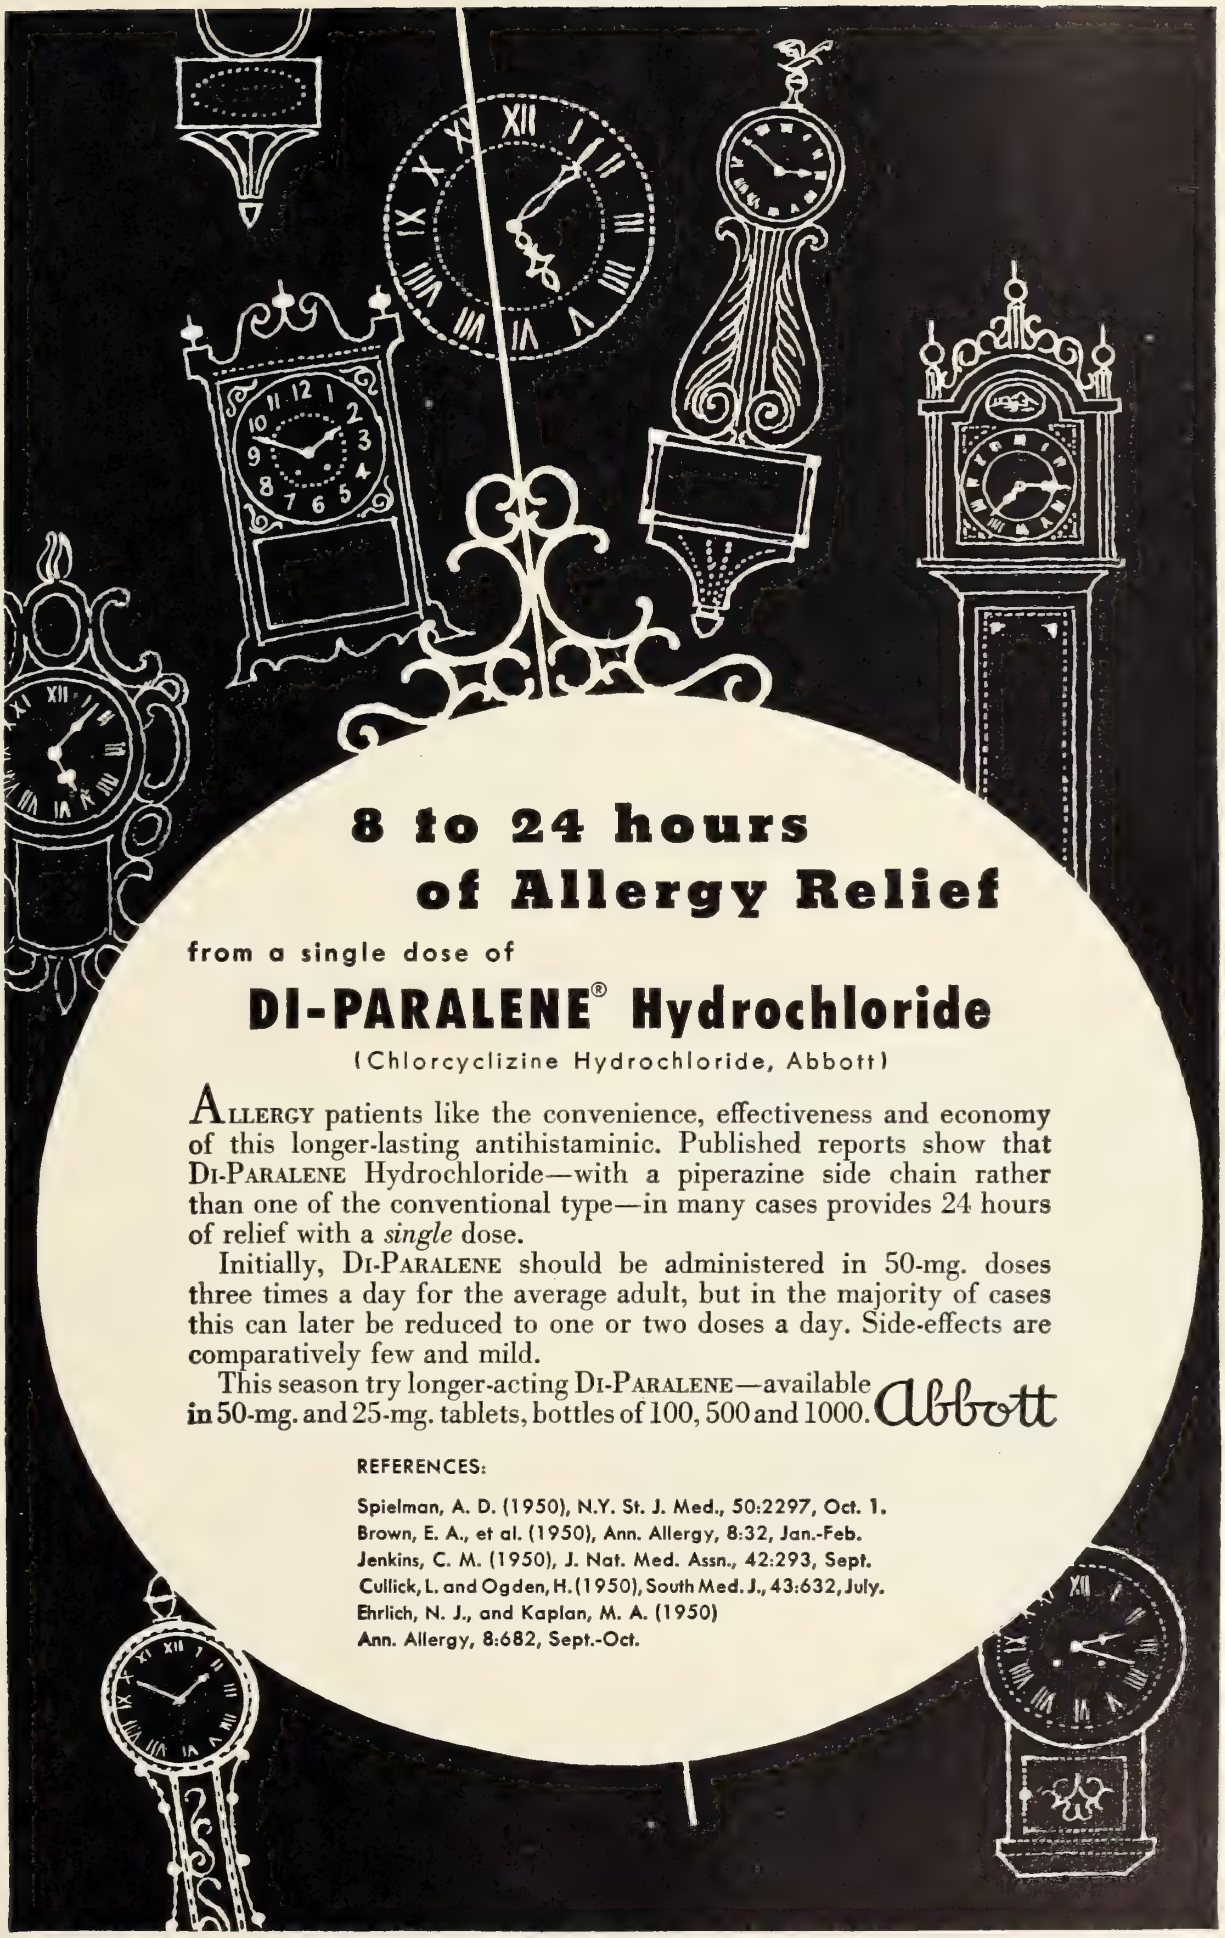
In 1903 an Anti-Tuberculosis Committee had been established in the Associated Charties of Minneapolis and in 1908 similar committees were organized in Saint Paul and Duluth.

In 1914 the Saint Paul Anti-Tuberculosis Committee was turned over to the United Charities of Saint Paul and in 1919 changed its name to the Ramsey County Public Health Association. In 1924 it became a subsidiary of the Minnesota Public Health Association and in 1943 became incorporated.

In 1916 the St. Louis County Public Health Association was first organized as a committee of the Minnesota Public Health Association. This Association was reorganized in February, 1919, under the same name, and a constitution and by-laws were adopted. In 1935 the name of the Association was changed to the Tuberculosis and Health Association of St. Louis County. It was incorporated in 1937.

In 1920 the Anti-Tuberculosis Committee of the Minneapolis Associated Charities became a separate incorporation known as the Hennepin County Tuberculosis As-

(Continued on Page 482)



8 to 24 hours of Allergy Relief

from a single dose of

DI-PARALENE® Hydrochloride

(Chlorcyclizine Hydrochloride, Abbott)

Allergy patients like the convenience, effectiveness and economy of this longer-lasting antihistaminic. Published reports show that Di-Paralene Hydrochloride—with a piperazine side chain rather than one of the conventional type—in many cases provides 24 hours of relief with a *single* dose.

Initially, Di-Paralene should be administered in 50-mg. doses three times a day for the average adult, but in the majority of cases this can later be reduced to one or two doses a day. Side-effects are comparatively few and mild.

This season try longer-acting Di-Paralene—available in 50-mg. and 25-mg. tablets, bottles of 100, 500 and 1000. Abbott

(Continued from Page 480)

sociation, and in 1948 the Ramsey County Public Health Association became the Ramsey County Tuberculosis and Health Association.

The publication of the state association changed its name in 1923 from the *Minnesota Public Health Association Journal* to the *Northwestern Health Journal*, and in 1929 the title *Everybody's Health* was adopted.

The State and County organizations are supported by Christmas Seal sales and not by taxes.

GENERAL PRACTICE POSTGRADUATE TRAINING

The General Practice Group of the University of Tennessee has established a postgraduate clinical training program for general practitioners. This has been approved by the American Academy of General Practice for its members.

The program is designed for the general practitioner on an individual basis, according to his individual needs. One week to one month of training is offered.

Each doctor will spend morning hours in his choice of any one of the University specialty fields. This will be active work at the resident level. The afternoons will be spent in the General Practice Clinic where the medical students get active general practice experience. Evenings are utilized in the emergency room of the John Gaston Hospital which is suprvised by members of the General Practice Staff.

General practitioners who would like to participate or who desire further information, may write to the General Practice Office, University of Tennessee, Memphis, Tennessee. There is no fee charged for this training.

SOCIETY FOR THE PREVENTION OF ASPHYXIAL DEATH, INC.

A patron of the Society for the Prevention of Asphyxial Death, Inc., interested in making the causes and prevention of asphyxia better known to Minnesota physicians, has kindly offered to donate a copy of "Art of Resuscitation," by Paluel J. Flagg, M.D., to the first 100 physicians who become members of the Society following the release of this information in MINNESOTA MEDICINE.

The Society for the Prevention of Asphyxial Death, Inc., has received the opproval of the AMA. Its president, Dr. Paluel J. Flagg, is an authority on the subject of artificial respiration and is the author of the book, "Art of Resuscitation." The volumes which will be presented to the first 100 new members of the Society will be autographed by the author. The book has received favorable reviews in various journals.

Physicians who wish to take advantage of this offer should make application for membership to the Society for the Prevention of Asphyxial Death, Inc., 2 East 63 Street, New York 21, New York. Membership dues are $5.00.

INTERNATIONAL ACADEMY OF PROCTOLOGY

The International Academy of Proctology will hold its fourth annual meeting in Chicago, June 6, 7, and 8, at the Edgewater Beach Hotel.

The first two days will be devoted to a Seminar presentation of papers relating to the colon and rectum. The entire day of June 8 will be devoted to a teaching film presentation of surgical techniques for diseases of the Colon, Rectum and Anus.

All physicians are cordially invited, whether or not affiliated with the International Academy of Proctology. There will be no registration fee.

AMERICAN COLLEGE OF CHEST PHYSICIANS

The Twelfth Congress of the International Union Against Tuberculosis and the Second International Congress on Diseases of the Chest sponsored by the Council on International Affairs, American College of Chest Physicians, will be held in Rio de Janeiro, Brazil, August 24 to 30.

Physicians wishing to present papers at the Rio Congresses on the subject of tuberculosis are requested to write to Professor Etienne Bernard, Secretary General, International Union Against Tuberculosis, 47 Rue de Courcelles, Paris, France, and those wishing to present papers on nontuberculous diseases of the chest (heart and lung) should communicate with Dr. Andrew L. Banyai, Chairman, Council on International Affairs, American College of Chest Physicians, 112 East Chestnut Street, Chicago 11, Illinois.

For further information, write Mr. Murray Kornfeld, Executive Secretary, American College of Chest Physicians, 112 East Chestnut Street, Chicago 11, Illinois.

AMERICAN CONGRESS OF PHYSICAL MEDICINE

The thirtieth annual scientific and clinical session of the American Congress of Physicial Medicine will be held on August 25, 26, 27, 28 and 29 at The Roosevelt Hotel, New York, N. Y. Scientific and clinical sessions will be given on the days of August 25, 26, 27, 28 and 29. All sessions will be open to members of the medical profession in good standing with the American Medical Association. In addition to the scientific sessions, annual instruction seminars will be held. These lectures will be open to physicians as well as to therapists, who are registered with the American Registry of Physical Therapists or the American Occupational Therapy Association. Full information may be obtained by writing to the American Congress of Physical Medicine, 30 North Michigan Avenue, Chicago 2, Illinois.

Minnesota Academy of Medicine

Meeting of January 9, 1952

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, January 9, 1952. Dinner was served at 7 p.m. and the meeting was called to order at 8:15 p.m. by Dr. T. A. Peppard, Chairman of the Executive Committee.

There were fifty-two members and two guests present. No business was transacted at this meeting.

Before introducing the speaker of the evening, Dr. Peppard made the following remarks:

"To be seen, the after-dinner speaker must stand up; to be heard, he must speak loudly; to be appreciated, he must sit down. I appear briefly tonight in the role of elder statesman, at the request of Howard Hengstler, my good friend for over forty years. I shall sit down shortly.

"The Academy of Medicine was organized in 1887. Dr. Hengstler was the sixty-sixth president of our organization. The roll call of your revered predecessors is replete with distinguished names: John Fulton, Parks Ritchie, Charles Wheaton, Perry Millard, William A. Jones, Archibald MacLaren, James E. Moore, Alexander Colvin, Eugene Riggs, Arnold Schwyzer, Arthur Hamilton, James S. Gilfillan, and Jennings C. Litzenberg, to mention a few.

"This is your organization, and you can make of it what you will. My fondest hope and wish for the society is that it be as near to the aspirations of the present and future members as it was to the hearts of those pioneers who built so wisely and so well. To this end the officers and executive committee are dedicated and I believe have taken a step in the right direction during the past year. I have confidence that the coming officers will continue along the same lines.

"I should like to suggest that each of you read the Articles of Incorporation and consider what contribution the Academy is making to medical progress in Minnesota, what contribution you individually are making to the Academy, and that each of you seriously endeavor to fulfill its purposes as expressed in the Articles.

"I now introduce Dr. William Howard Hengstler, the retiring President, who will speak to you on the subject: 'Psychiatric Implications of the Atomic Age' Dr. Hengstler." (See page 405.)

The meeting was adjourned.

Wallace P. Ritchie, M.D., *Secretary*

design achievement
in treatment room furniture

New Steeline has gone through fifteen years of gradual development to reach the fine degree of design perfection it now has. The suggestions of scores of physicians and the engineering skill of our own production plant have been combined to produce this outstanding treatment room equipment. New features such as foam rubber cushioned contour top, magnetic door latches, concealed paper sheeting holder, superb color finishes, etc., are all fully described and illustrated in our new full-color brochure—send for yours today.

Migraine In Children

"Migraine may appear during the first years of life. The presence of subjective signs, such as headache and flimmer scotoma, is often difficult to determine in young children. The true nature of the symptoms frequently remains obscure for years."

Vahlquist, B. and Hackzell, G.: Acta Paediatrica *38*: 622 (1949).

NO. OF CASES	SEX	AGE AT ONSET	CYCLIC VOMITING	DURATION OF ATTACK	INTENSITY
31	8 ♀ 23 ♂	3 yrs. (mean)	3 out of 31	2½ hrs.	severe in all cases

TABLE CONT'D

NO. OF CASES	UNILATERAL HEADACHE	NAUSEA	FLIMMER SCOTOMA	VERTIGO	HEREDITY
31	18 out of 31	31 out of 31	12 out of 31	6 out of 31	20 out of 31

(reference given above)

In a study of 400 adult migraine patients, it was revealed that 34% had suffered attacks before the age of 15.* These investigators concluded that childhood migraine was a much greater clinical problem than was previously believed and that psychodynamic mechanisms played an important part in the disease.

These criteria are useful in diagnosis:

Headache attacks with symptom-free intervals plus (at least two of the following) nausea, scintillating scotoma, hemicrania, and hereditary predisposition.

For symptomatic relief in these cases, Cafergot®, N.N.R. (ergotamine with caffeine) may be administered orally. For best results, give adequate dosage promptly.

For children within the age range 7 to 12 years—Cafergot® is administered, one tablet when the attack appears imminent followed by one additional tablet within 30 minutes. Not more than two Cafergot tablets should be administered to children within this age range.

In the adolescent age group, 12 to 18 years of age, the dosage may gradually be increased as necessary up to the usual adult dose, i.e., two tablets when the attack appears imminent followed by one tablet doses at half hour intervals until the attack is aborted. *(Total maximum dose for adults: six tablets for each attack.)*

Woman's Auxiliary

NATIONAL AUXILIARY ANNOUNCES ANNUAL MEETING

A cordial invitation is extended to all members of the Woman's Auxiliary to the American Medical Association, their guests and guests of physicians attending the convention of the American Medical Association, June 8-13, to participate in all social functions and attend the general sessions of the Auxiliary.

Headquarters will be at Conrad Hilton Hotel, Chicago, Illinois. Tickets will be available at the registration desk only. Please register early and obtain badge and program.

Committee meetings will be held on Sunday, June 8, at the Conrad Hilton Hotel. On Monday morning Round-Table Discussions on Program, Legislation, Public Relations and Today's Health will be held. Also, the meeting of the Board of Directors and its luncheon will be held on Monday. A tea in honor of Mrs. Harold F. Wahlquist, President, and Mrs. Ralph Eusden, President-Elect, will be held on Monday afternoon.

The formal opening of the twenty-ninth annual meeting will be at 9 a.m. on Tuesday, June 10, at the Conrad Hilton Hotel. The presidential address by Mrs. Harold F. Wahlquist will be given at this session. Officers will present reports prior to the 12:30 p.m. luncheon, at which Dr. Laurence M. Gould, president of Carleton College, Northfield, Minnesota, will be the featured speaker. At the afternoon session, members will hear reports of state presidents, chairmen of standing committees, and preliminary reports of the Nominating Committee.

Wednesday's general session will present the remainder of state reports and standing committee chairmen. Featured will be a radio broadcast by two doctors' wives from Minnesota: Mrs. Ralph Creighton and Mrs. L. J. Leonard, both of Minneapolis. After the reports of chairmen of special committees, the annual luncheon will be held.

Election of officers will be held on Thursday, June 12, after which the installation of officers, presentation of past president's and president's pin and the inaugural address will take place. The afternoon session will include a meeting of the Board of Directors.

A conference of national officers, directors, national chairmen of standing committees and state presidents and presidents-elect will be held on Friday morning.

General chairman for the annual meeting is Mrs. Warren W. Young.

ST. LOUIS COUNTY HOLDS HEALTH DAY

The St. Louis County Medical Auxiliary Health Day was presented at a meeting for Duluth high school teachers on Saturday, March 1. Approximately 350 teachers attended, including representatives from the elementary schools, the parochial high schools, the

North Shore Health Resort

Winnetka, Illinois

on the Shores of Lake Michigan

public schools of Cloquet, Proctor, Two Harbors, Minnesota, and Superior, Wisconsin; the University of Minnesota, Duluth Branch, and Superior State Teachers College.

The morning session was a symposium on mental health, specifically on the problems of authority from the viewpoints of the teacher and the student. Dr. C. Knight Aldrich and Miss Lydia Hermann from the University of Minnesota were the speakers, and Mr. Frank W. Hanson, University of Minnesota, Duluth Branch, was the moderator. The afternoon session included a talk by Dr. P. G. Boman, Duluth, on the dangers of self-medication and a discussion of the principles of selection for exercise by Dr. Elizabeth Graybeal, head of Women's Physical Education at the University of Minnesota, Duluth Branch.

Exhibits were arranged by Miss Florence Maney, Director of the School Art Department, and Miss Alice Huisenfeldt, Director of School Nurses.

Factual literature on mental health, cancer, polio, safety, tuberculosis, rheumatic fever and prevention of blindness was arranged for and distributed by the auxiliary committee. Copies of the November, 1951, issue of *Today's Health,* containing an article on mental health for teachers, were given to each member of the audience.

Question and discussion periods at the end of each session showed an active interest by the audience, and comments from the Board of Education and many of the teachers have been most enthusiastic.

In Memoriam

WARD AKESTER

Dr. Ward Akester, who practiced many years at Marshall, Minnesota, died March 27, 1952, at Veterans Hospital, Minnesota, at the age of seventy-one.

Dr. Akester graduated from the Medical College of Indiana in 1902. He had practiced medicine for fifty years, most of the period at Marshall. After leaving Marshall a few years ago he served on the staff of the state hospital at Fergus Falls until last September when he joined the staff of the Mt. Pleasant State Hospital in Iowa.

He was a veteran of World Wars I and II. He was formerly a member of the Lyon-Lincoln County Medical Society, The Minnesota State Medical Association and the American Medical Association. Mrs. Akester survives him.

HENRY G. HENRIKSEN

Dr. Henry G. Henriksen of Northfield died March 30, 1952. He was eighty-two years of age.

Dr. Henry G. Henriksen was born at Stavanger, Norway, June 6, 1869. He attended Kongsgaard College at Stavanger, but obtained his M.D. degree from Bennett Medical College in Chicago in 1897.

After practicing in Iowa from 1898 to 1910 he moved to New Market, Minnesota, in May, 1910, where he practiced until May, 1921. He practiced in Elko, Minnesota, from June 1923 to September, 1938, when he moved to Northfield.

Dr. Henriksen was a member of the Scott-Carver County Medical Society, the Minnesota State Medical Association and the American Medical Association. He is survived by his widow.

AENAS E. MACDONALD

Dr. A. E. Macdonald of Minneapolis died April 11, 1952, at the age of seventy-six.

Born in Ontario, Canada, April 6, 1876, he obtained his preliminary education at Kingston High School and his M.D. degree from Queen's University at Kingston. He interned at Ottawa General Hospital and took post-graduate study at Harvard Medical School and at the Policlinic in Chicago. He practiced at Morristown for thirteen years before moving to Minneapolis.

Dr. Macdonald was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

ARNOLD EDWIN JOHNSON

Dr. A. E. Johnson, Red Wing, died in Minneapolis on March 27, 1952. After forty-two years of practice, he retired four years ago. While in California on a trip, he became ill and spent many weeks in a hospital in Los Angeles before returning to Minnesota.

Dr. Johnson was born in Kasson, Minnesota, June 23, 1876. He graduated from Rush Medical College in 1902 and settled in Red Wing where he devoted himself to general practice. He was first associated with Drs. Cremer and Claydon before establishing his own clinic, the Red Wing Clinic. He played a large part in the establishment and growth of the Red Wing hospital, now the City Hospital. He was a member of the Goodhue County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Johnson is survived by his wife and three children, Juel of Glendale, California, Mrs. Elaine Barrington of Minneapolis and Kenneth of Little Falls.

Of General Interest

A news release from the American College of Radiology, under the date of May 1, 1952, calls attention to the **possibility of hypervitaminosis** as a result of overdosage with vitamin A. Currently, twenty-two examples of chronic vitamin A poisoning have been reported in infants and children, the symptoms being loss of appetite, itching and fretfulness. Additional symptoms reported include fissure of the lips, loss of hair, dry skin, jaundice and enlargement of the liver. Self-medication was responsible for the only case of poisoning in an adult so far reported.

Dr. Walter Halloran, Jackson, was among those who attended a section meeting of the American College of Surgeons at the Radisson Hotel, Minneapolis, on March 24.

* * *

Dr. E. T. Bell, emeritus professor of pathology at the University of Minnesota Medical School, was presented with a medal and citation by the Minnesota Division of the American Cancer Society at a luncheon meeting on April 9 at Hotel Nicollet, Minneapolis. The award was made for Dr. Bell's outstanding service in cancer control. The presentation was made by **Dr. C. G. Uhley,** Crookston, president of the Minnesota Division of the society.

Dr. Bell was a native of Missouri and joined University faculty in 1910. He retired as chief of the Department of Pathology in 1949. However, he continues his research in his laboratory and spends two days a week as consultant at the Minneapolis Veterans Hospital.

Former recipients of the cancer society award are **Dr. Owen Wangensteen, Dr. John J. Bittner** and **Dr. Arthur Kirschbaum.**

* * *

Dr. Stewart W. Shimonek, after a period of nearly two years of re-enlistment in the Navy, has reopened his office at 439 Lowry Medical Arts Building, Saint Paul, for the practice of orthopedic surgery.

Eli Lilly and Company, in accordance with its long-established policy, has been replacing all Lilly products in pharmacies and hospitals ravaged by floods in the Missouri and Mississippi River valleys. Lilly representatives in a dozen states, from Montana to Missouri, were directed to make the replacement of flood-damaged Lilly pharmaceuticals and biologicals their first order of business. Lilly has been replacing stocks damaged by uninsurable hazards as fas back as the 1906 San Francisco disaster.

Along with the replacement of stocks, the Lilly company maintains a reserve supply of typhoid vaccine and other biological products which is kept ready for fast shipment during disasters. The shipping personnel of the company stands by twenty-four hours a day.

* * *

Dr. Edward H. Lambert, Rochester, is the first recipient of the Arnold D. Tuttle Memorial Award, which is to be given annually to the author of the best research paper published during the year in the *Journal of Aviation Medicine.* Dr. Lambert received the award in Washington on March 19.

* * *

Mr. Robert T. Bruss of Rolla, Missouri, a medical student at the University of Minnesota, has been awarded a research fellowship of $1,200 by the Public Health Service through the National Heart Institute for a study of cardiac excitability simulating clinical conditions. Another University of Minnesota student, **Howard H. Shear,** Saint Paul, has been awarded a research fellowship of $1,600 by the Public Health Service through the National Cancer Institute for study of an accelerant for mouse mammary cancer.

* * *

Dr. R. F. Pierson, Slayton, has announced that **Dr. J. L. Bader,** a graduate of the University of Nebraska Medical School, will join the staff of the Slayton Clinic on July 1.

* * *

Dr. Fred L. Adair, formerly of Minneapolis and now living at Maitland, Florida, has retired as president of the American Committee on Maternal Welfare. He had been president since the committee was incorporated in 1934. He was also one of the founders and key figures of the Joint Committee on Maternal Welfare, formed in 1919, which broadened into the present organization. Dr. Adair has been succeeded as president by **Dr. Frederick H. Falls,** Chicago.

When Is A Dollar A Dollar?

It is quite common today to hear about a "50c dollar"—a dollar that buys what only 50c would buy in the past.

Many people, however, have not heard about the "60c dollar"—a dollar of investment income that shrinks to 60c after income taxes are paid.

Two men in similar financial circumstances ($12,000 taxable income bracket for example) are each receiving income from investments:

One man receives a "60c dollar."
The other receives a "$1.00 dollar."

WHY?

Income from corporate bonds and stocks, government bonds, contracts for deed, mortgages and most other investments is subject to our present Federal Income tax.

Income from Municipal Bonds is exempt from such tax.

ARE YOU INTERESTED IN RECEIVING A "$1.00 DOLLAR" FROM YOUR INVESTMENTS?

Write or call for descriptive circulars of municipal bonds we are currently offering.

used in Yugoslavia as part of the program there for improving services to the chronically handicapped.

Yugoslavia, which has a specially aggravated problem in physical rehabilitation because of the double impact of a hard mountain war against the Nazis and local health conditions, asked the United Nations for help in this field over a year ago. The Technical Assistance Administration sent **Dr. Henry H. Kessler,** orthopedic surgeon and physical rehabilitation specialist, of Newark, New Jersey, to the country for an intensive survey of the problem and present practices in returning the handicapped to as normal a life as possible. He returned with a deep regard for the accomplishments of the professional personnel of the country under tremendous handicaps. He said, for example, that he would be proud to achieve the record of a surgeon he met who had not lost a patient in hundreds of operations without having any of the operating room facilities he, Dr. Kessler, considered normal and essential.

Dr. Kessler reported to the Yugoslav government that their central need was for an integrated approach to the patient. He recommended the training as a team of eight persons concerned with all phases of the patient's return to a useful life. The Yugoslav government agreed and named its candidates. They were awarded training fellowships under the UN technical assistance program and have now completed their studies. Dr. Kessler's own Physical Rehabilitation Institute in West Orange, New Jersey, was one of the stops on the training tour.

Upon the return to Belgrade of the team of eight, they were installed by the government as a faculty of a training institute to turn out personnel for services to the handicapped in the provincial centers. It is in furtherance of this internal training program that the Yugoslav government asked for training films and literature, and that the United Nations acquired Dr. Hart's film to meet the Yugoslav need.

The Technical Assistance Administration is now dispatching an average of an expert a day to countries in all parts of the world to meet the requests of governments in other social welfare fields, in power production, transportation, and other economic services, and in all types of public administration. Experts have been employed from thirty-five countries. Training opportunities are also being awarded at the rate of fifty to sixty a month. **Dr. Hugh L. Keenleyside** of Canada is director-general of the Technical Assistance Administration.

Lake Chisago, Center City, Minn. Telephone 83

Dr. Ronald W. Barr, formerly of Sioux Falls, South Dakota, has joined the staff of the Montevideo Clinic. A graduate of the University of Minnesota Medical School, Dr. Barr practiced at Sioux Falls for four years before moving to Montevideo.

* * *

Dr. W. F. Mercil, Crookston, attended a joint meeting of the American Committee on Maternal Welfare and the American Academy of Obstetrics and Gynecology at Cincinnati, Ohio, during the first week of April.

* * *

Plans for a "walking blood bank" in the Cloquet community were announced on April 1 by **Dr. Paul B. Monroe**, Cloquet. The plan called for determining and recording the blood type of each of several hundred volunteer donors. Then in case of emergency in the city, it would be easy to locate proper donors quickly for direct transfusions. Under the plan it would be unnecessary to set up a standard blood bank with storage facilities Dr. Monroe pointed out.

* * *

Dr. S. W. Giere, Benson, escaped the rigors of late winter for a few weeks by taking a vacation in Mexico. He returned to Benson during March.

* * *

Dr. Warren W. Haesly, formerly of Wykoff, has moved to Rushford and opened offices for the practice of medicine. A native of Winona, Dr. Haesly received his medical training at Northwestern University and interned at St. Luke's Hospital, Chicago, where he also did some postgraduate work in urology and pediatrics.

* * *

Dr. H. A. Palmer, Blackduck, gave a refresher course in first aid to members of the Blackduck fire department and other interested persons on March 25. Included was a demonstration of the use of a resuscitator.

* * *

Dr. and Mrs. James B. McBean, Rochester, and their four daughters spent the month of April on a vacation trip to England, where they visited Mrs. McBean's family. During their trip they also toured Paris and Ireland.

* * *

Formerly of Scribner, Nebraska, **Dr. Herbert G. Ahrens** has joined the staff of the Worthington Clinic. A graduate of the University of Nebraska, Dr. Ahrens interned at Emanuel Hospital, Omaha, and then served in the Army for two years during World War II. He then completed a three-year fellowship in internal medicine at the Mayo Foundation, after which he practiced at Scribner for a year before moving to Worthington.

* * *

The seventeenth annual John W. Bell tuberculosis lecture was given by **Dr. Esmond R. Long**, Philadelphia, at a meeting of the Hennepin County Medical Society in Minneapolis on April 7. Dr. Long is director of the Henry Phipps Institute and director of medical research for the National Tuberculosis Association.

* * *

In Glenwood **Dr. J. T. Gericke** has moved into newly remodeled offices designed for efficiency and pleasing appearance. Dr. Gericke has practiced at Glenwood for six years.

* * *

Dr. Edgar V. Allen, Rochester, was named a vice president of the American Heart Association at a meeting of the organization in Cleveland during the middle of April.

* * *

An annual award to the physician who had attended and taken part in the greatest number of postgraduate medical and surgical clinics during the past year at the University of Minnesota Center for Continuation Study was presented to **Dr. G. F. Engstrom,** Belgrade, on April 9.

* * *

Dr. Frederick D. Roth, formerly of Lewiston, has joined the Mankato Clinic and is affiliated with its department of ophthalmology. A graduate of Marquette University, Dr. Roth recently completed three years of postgraduate training at Boston City Hospital. Before his hospital residency in Boston he was in general practice at Lewiston.

Dr. John Fischer, formerly of Owatonna, has purchased the practice of **Dr. H. J. Kurtin** and **Dr. J. J. Kurtin** at Blooming Prairie.

Dr. H. J. Kurtin, who began practice at Blooming Prairie in 1940, is going to begin this summer a two or three year course in ophthalmology and otolaryngology at Harvard Medical School. Dr. J. J. Kurtin, who joined his brother in practice in 1950, expects to go into military service with the Army. Until called, however, he plans to be a resident in pathology at St. Mary's Hospital, Milwaukee.

Dr. Fischer, a graduate of Washington University School of Medicine, St. Louis, has been associated in practice for the past two years with Dr. John McIntyre at Owatonna.

* * *

Dr. N. M. Mensheha became associated in practice with **Dr. J. A. Poirier** at Forest Lake on April 1. Dr. Mensheha, who recently completed one and one-half years of study at Bethesda Hospital, Saint Paul, is a native of the Ukraine. He came to the United States less than three years ago. In that time he has learned to speak English fluently and has passed the necessary medical examinations for licensure. He is a graduate of the University of Munich.

* * *

After seventeen years of practice at Lakeville, **Dr. Kenneth E. Stein** announced early in April that he planned to move to Pierz to become associated

MINNESOTA BLUE CROSS-BLUE SHIELD PLANS

In a recent review of Blue Shield claims, it was found that eleven involving Workmen's Compensation and one involving Veterans care eligibility had been paid. In such cases, the contract excludes from Blue Shield coverage any claims for which full or partial payment has been made under the Workmen's Compensation Act or by the Veterans Administration. To secure needed information in these cases two questions requiring a "yes" or "no" answer appear in the Medical Service Report, one asking if the claim is covered by Workmen's Compensation and the other asking if Veterans' benefits apply in the case.

Analyzing the claims, it was found that in six cases the "No" was checked and in six cases neither the "Yes" nor the "No" was checked. This indicates that in all twelve cases inadequate information to handle the case properly was received in the Medical Service Report. In other words, there was no evidence that eleven cases involved Workmen's Compensation nor that one case might have Veteran's benefits.

Further investigation revealed that Veterans' benefits were not available in the one case, and in only three of eleven cases reported as covered by Workmen's Compensation had an award of compensation been made. In each of the three cases covered by Workmen's Compensation, in order to avoid misuse of funds by the paying of such unwarranted claims, it has been necessary to request a refund from either the doctor or subscriber. In one instance no payment was received by the doctor from any other source, so a refund has

been requested from the subscriber. In the remaining two cases, no reply regarding other payment has been received from the attending doctor and further action in these cases is pending.

The Blue Shield office is anxious to avoid the necessity of requesting refunds in such cases. From the foregoing facts, it is apparent that the co-operation of physicians is vitally necessary in answering all questions which appear on the Medical Service Report. This would save considerable time and expense, and also it would avoid misunderstanding by both physician and subscriber.

Constant efforts are being made to eliminate duplicate requests for information in processing Blue Shield and Blue Cross claims. Recently, a form letter has been adopted to be used in obtaining the medical history necessary to processing a claim presented within the first ten months of the contract's effective date. This form letter is sent to the doctor in duplicate. *Both the original and the copy* should be returned to the Blue Cross-Blue Shield office where one copy becomes part of the Medical Claim file, and the other copy becomes part of the Hospital Admission Department record. It is hoped that this process will suffice in giving identical information regarding both medical and hospital claims, and also will eliminate any duplicate questionnaires which the attending physician may have previously been requested to complete.

Blue Cross Activities

James E. Stuart, executive director, Hospital Care Corporation, Cincinnati, was elected chairman of the Blue Cross Commission at the Commission meeting held on April 3, in San Francisco, following the 1952 Annual Conference of Blue Cross Plans, March 30 to April 3. He succeeds William S. McNary, executive vice president, Michigan Hospital Service, Detroit.

J. Philo Nelson, executive director, Hospital Service of California, Oakland, succeeded Stuart as vice chairman of the Commission while Abraham Oseroff, vice president, Hospital Service Association of Pittsburgh, was re-elected treasurer.

Stuart has served as executive director of the Cincinnati Blue Cross Plan since 1942. Prior to that time he was director of public welfare, Hamilton County (Cincinnati) for two years; associate director of the Hamilton County Community Chest for three years; and executive director of the Child Welfare Board for four years.

John R. Hill, executive director, Tennessee Hospital Service Association, Chattanooga; Robert T. Evans, executive director, Blue Cross Plan for Hospital Care, Chicago; Arthur M. Calvin, executive director, Minnesota Hospital Service Association, St. Paul; D. W. Ogilvie, director, Blue Cross Plan for Hospital Care, Toronto, were elected to the Commission to succeed W. W. McCrary, Jr., Memphis; Wm. S. McNary; Leon R. Wheeler, Milwaukee; and E. Duncan Millican, Montreal, respectively.

Rt. Rev. Msgr. George Lewis Smith, Diocesan Director of Catholic Hospitals in South Carolina, Aiken, was named to serve on the Commission as one of the three representatives of the American Hospital Association, replacing Dr. W. B. Seymour, director, University Hospitals of Cleveland.

PANCREATITIS

(Continued from Page 419)

severe, more prolonged attacks of pain, prominent physiological alterations in glucose metabolism and by development of steatorrhea.

When radiological evidence of calcification of the pancreas is found, the diagnosis is clear. Treatment, suffice it to say, is generally disappointing. Paravertebral injections, as mentioned before, may control the acute pain. Surgical therapy is none too satisfactory. Long continued biliary drainage, anastomosis between the common bile duct and duodenum and between the pancreatic duct and the duodenum, section of the sphincter of Oddi, partial and total pancreatectomy and sympathectomy, splanchnicectomy and vagotomy have been helpful in relieving pain and preventing the recurrence of attacks in some instances. Whipple, in 1946, collected reports of twelve cases of total pancreatectomy from the literature and added two of his own for this condition. This is a heroic procedure with a great morbidity and high mortality rate and would appear to be justified only in an occasional patient with intractable pain, perhaps already diabetic. Before carrying out such an extensive procedure, consideration should be given to less serious operations such as section of the nerves: ganglionectomy on the right side (7th to 12th) with or without resection of the right splanchnic nerve, which have been advocated.

Conclusions

In conclusion, I would like to re-emphasize that:

1. Pancreatitis is a much more common disease than generally acknowledged. This increase is a relative one since the diagnosis is more frequently made in recent years because of the serum amylase test.

2. The serum amylase test should be routine in all cases of acute intra-abdominal emergencies but we should also bear in mind its limitations and irregularities.

3. There is such an entity as chronic relapsing pancreatitis as first described by Comfort in 1946.

4. Conservative therapy is in general the best policy except in those few cases of the hemorrhagic type with definite surgical indications.

In infant formulas...

proper

caloric

distribution

calls for

adequate added carbohydrate

FREQUENT mention in authoritative pediatric literature supports the classic caloric distribution of 15% protein, 35% fat and 50% carbohydrate for infant formulas.

This assures ample protein for development of sound tissue structure. And it supplies *adequate carbohydrate* to spare protein for its essential functions, meet energy needs, promote good fat metabolism and maintain water balance.

This classic caloric distribution is conveniently represented by 1 part evaporated milk and 2 parts water with 5 per cent added carbohydrate—roughly 1 tablespoon of Dextri-Maltose to each 5 ounces of formula.

For over 40 years, milk and Dextri-Maltose formulas with these approximate proportions have enjoyed consistent clinical success.

n pelvic inflammatory disease......

CHLOROMYCETIN produces prompt clinical response in the mixed infections commonly found in pelvic inflammatory disease. "In mixed infection [pelvic cellulitis and abscess] CHLOROMYCETIN appears to be superior to penicillin, streptomycin or sulfadiazine."[1]

"The clinical response to chloramphenicol consisted of marked symptomatic improvement, usually within 48 hours. . . .

"Women who had large pelvic abscesses were treated so effectively with chloramphenicol that posterior colpotomy, with drainage of the abscess, was not necessary in effecting a rapid cure in any of our patients who were treated with this antibiotic from the start."[2]

CHLOROMYCETIN (chloramphenicol, Parke-Davis) is supplied in a variety of forms including:

CHLOROMYCETIN	Kapseals®, 250 mg., bottles of 16 and 100.
CHLOROMYCETIN	Capsules, 100 mg., bottles of 25 and 100.
CHLOROMYCETIN	Capsules, 50 mg., bottles of 25 and 100.
CHLOROMYCETIN	Ophthalmic Ointment, 1%, ⅛-ounce collapsible tubes.
CHLOROMYCETIN	Ophthalmic, 25 mg. dry powder for solution, individual vials with droppers.

Look at Your Income This Way

You can't lock it up in a vault to protect it. Yet it is more important than any personal property that you may own, and if anything should happen to it, you would stand to lose plenty.

It is logical that this plan of your Association, using its buying power, can do more for you than any individually purchased policy. Mute testimony for that point is the many professional organizations that have investigated and tested this special plan of disability insurance.

You can't eat accident and sickness insurance, but it will certainly keep you from starving.

DELAY offers no advantage—CALL US NOW!

You pay only for results. Our fee is 25 per cent of the monies you so receive. There are no binding contracts or inconveniences on your part.

Let us recover monies due you by sending us your list of delinquent accounts.

NATIONAL RATING ASSOCIATION
2126 Mishawaka Avenue
South Bend 15, Indiana

Established 1901

From among all antibiotics, Orthopedic Surgeons often choose

New aureomycin minimal dosage for adults—four 250 mg. capsules daily, with milk.

AUREOMYCIN

Hydrochloride Crystalline

because

Aureomycin, following oral administration, diffuses rapidly into the skeletal and structural tissues of the body.

Aureomycin exhibits little tendency to favor the development of resistant bacterial strains.

Aureomycin in daily repeated small dosage gives satisfactory serum levels, and may be continued over a long period.

Aureomycin has been reported to be clinically effective against susceptible organisms in the following conditions frequently seen by the orthopedic surgeon:
Suppurative Arthritis • Osteomyelitis
Infected Compound Fractures • Osteitis
Brucella Arthritis • Periostitis

Throughout the world, as in the United States, aureomycin is recognized as a broad-spectrum antibiotic of established effectiveness.

Capsules: 50 mg.—Bottles of 25 and 100; 250 mg.—Bottles of 16 and 100. *Ophthalmic:* Vials of 25 mg. with dropper; solution prepared by adding 5 cc. of distilled water.

FIRST RESORT
in NONSPECIFIC PROCTITIS *and* ULCERATIVE COLITIS

ACCEPTED
COUNCIL ON PHARMACY AND CHEMISTRY
AMERICAN MEDICAL ASSOCIATION

Negative results with certain other forms of therapy have prompted many physicians to turn to NISULFAZOLE as a "last resort"—only to discover that it should have been their first approach to NONSPECIFIC ULCERATIVE PROCTITIS and COLITIS.

NISULFAZOLE frequently brings striking initial improvement in these cases . . . reduction in number of stools often occurring within the first 24 hours. Administered intrarectally, NISULFAZOLE exerts "focal" action at the site of the disease. The high incidence of remission of symptoms following NISULFAZOLE therapy is a source of gratification to physician and patient alike.

SCHERING

They'd make quite a family reunion...

...the 44 patients who represent each of the many conditions for which short-acting NEMBUTAL is effective.

EVEN IF YOU'VE TRIED short-acting NEMBUTAL in no more than a few of its 44 uses, the advantages would still be apparent.

You would already know, for example, how adjusted doses of short-acting NEMBUTAL can achieve any desired degree of cerebral depression, from mild sedation to deep hypnosis.

You would be familiar with the rapid onset, the brief duration, the rare incidence of cumulative effect and "hangover".

And, more important, you would know that short-acting NEMBUTAL's smaller dosage—only about *half* that required by many other barbiturates—results in less drug to be inactivated, marked clinical safety, definite economy to the patient.

For further information, why not write for your copy of the new booklet, "*44 Clinical Uses for* NEMBUTAL". Just address a card to Abbott Laboratories, North Chicago, Illinois.

"therapeutic bile"
overcomes stasis

what is "therapeutic bile"?

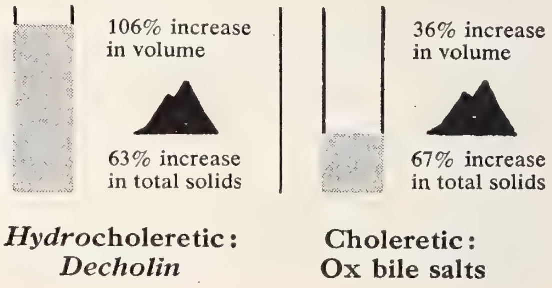
Thin, free-flowing bile in copious amounts as produced by *hydro*choleresis with *Decholin.*

what does "therapeutic bile" do?

Overcomes stasis in chronic cholecystitis and noncalculous cholangitis by flushing thickened bile, mucus plugs and debris from the biliary tract.

how does "therapeutic bile" differ from other bile?

"THERAPEUTIC BILE" is higher in fluid content and lower in solid content than bile produced by choleretics, e.g., ox bile salts.



DECHOLIN®
(brand of dehydrocholic acid)

how is "therapeutic bile" obtained?

"THERAPEUTIC BILE" is obtained by adequate dosage of *Decholin* and *Decholin Sodium.* Most patients require one or two tablets t.i.d. for four to six weeks. Prescription of 100 tablets is recommended for maximum efficacy and economy. More prompt and intensive *hydro*choleresis may be achieved by initiating therapy with *Decholin Sodium* 5 cc. to 10 cc. intravenously, once daily.

Decholin Tablets, 3¾ gr. (0.25 Gm.),
bottles of 100, 500, 1000 and 5000.

Decholin Sodium (brand of sodium dehydrocholate)
20% aqueous solution, ampuls of 3 cc., 5 cc. and 10 cc.

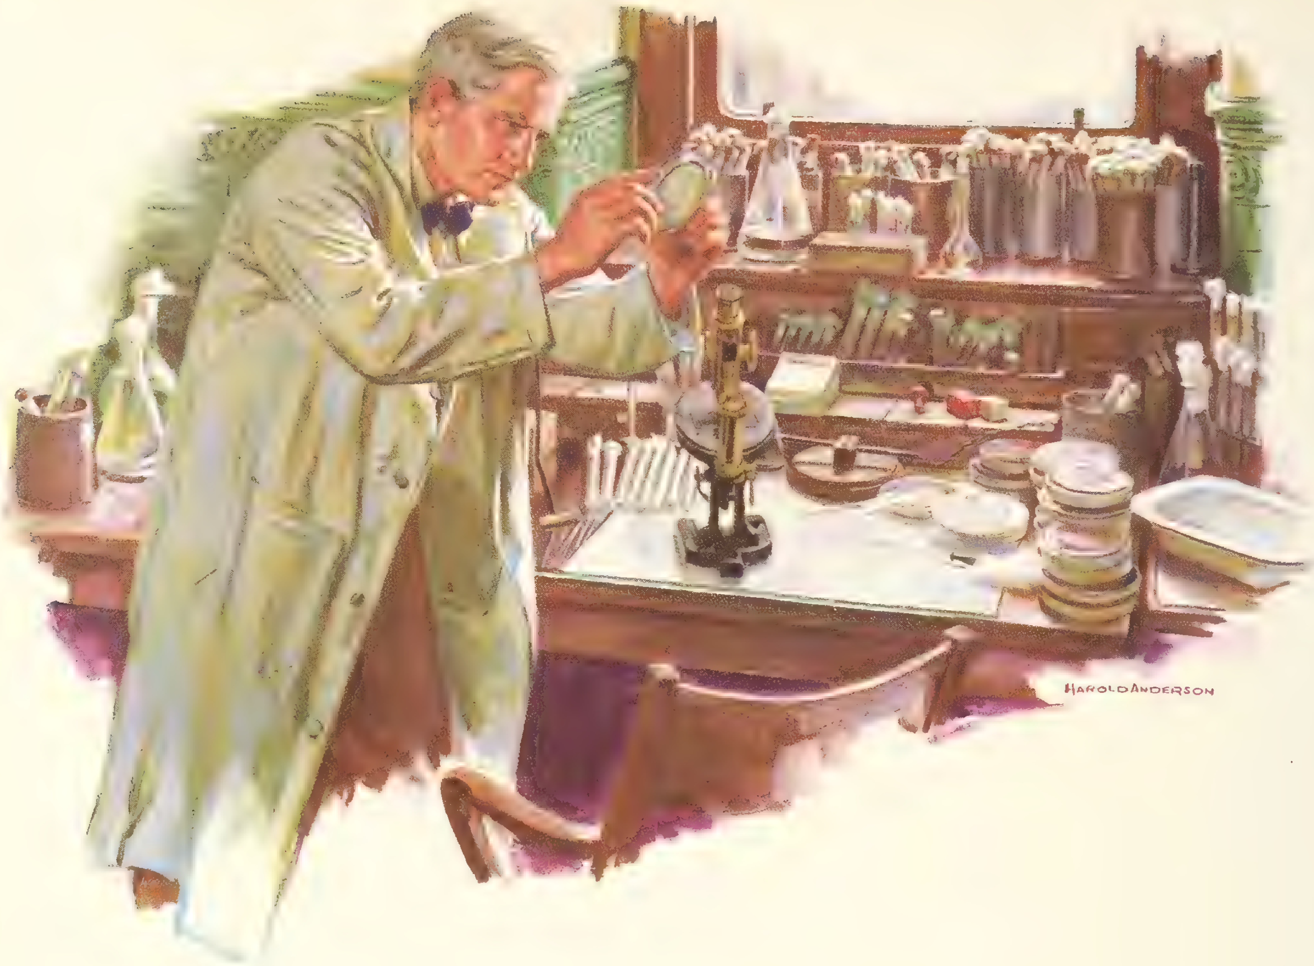
"Please come in, Doctor Harris . . . . . . Now everything is going to be all right"

Dr. Harris is a modest man. He may not even be aware that this is one reason why his patients have so much confidence in him. Another is his complete willingness to sacrifice his own comfort for their welfare. In his humility he has often said, "I just wasn't able to do as much as I wanted." In recent years, however, the odds in his struggle against disease and death have been immensely bettered by such powerful new weapons as the antibiotics. Penicillin, the first of these to be offered him by his ally, the pharmaceutical industry, was discovered by chance and nearly lost by an accident . . . →

Lilly



... poured in the sink—almost!

Sir Alexander Fleming's discovery of penicillin nearly met with an accident which might have delayed the benefit of this product indefinitely. The unexpected growth of mold was almost dumped into the sink; it was saved only because of scientific curiosity.

Some time after Fleming's discovery, large-scale production was undertaken to meet the tremendous wartime needs for penicillin. Improvements which were developed in the Lilly Laboratories substantially increased the yield. More recently, a development in penicillin research has made it possible to treat in the office or home many patients who otherwise would require hospitalization. By eliminating the need for more frequent injections, this advancement has saved thousands of hours for physicians and their assistants.

In addition to seeking new products, Lilly research improves existing medicines in order to provide more efficient therapy.

LUMBAR SYMPATHECTOMY IN THE TREATMENT OF PERIPHERAL ARTERIOSCLEROSIS OBLITERANS

FREDERICK M. OWENS, JR., M.D., F.A.C.S.

Saint Paul, Minnesota

LUMBAR sympathectomy has been employed with increasing frequency during the past decade in the treatment of peripheral arteriosclerosis obliterans. The rational of this treatment has been well expressed by Freeman, Leeds and Gardner,[7] who stated in 1947 that the "purpose of sympathectomy in the treatment of peripheral vascular disease is manifestly to abolish vasomotor tone in order to allow development of collateral blood vessels." Considerable discussion continues at present, both pro and con the use of sympathectomy in this disorder. Thus a series of cases will be presented in an attempt to add objective data to the accumulated information on this subject.

The pathologic changes occurring in peripheral arteriosclerosis obliterans can be divided into two general categories: (1) the progressive decrease of the size of the lumen of smaller vessels, and (2) the decrease of lumen size of major vessels. In the first group are included vessels the size of the distal femoral artery and all smaller arteries. In the second group are included the aorta, the iliac and proximal portion of the femoral arteries. At the present time the most satisfactory treatment of the first group, the smaller vessels, is sympathectomy, while the latter group of cases can be treated by sympathectomy but also by intimectomy or endarterectomy. Another method of treatment being attempted in the latter group is resection of the diseased segments and replacement by artery grafts. This is applicable where the block is regional and the distal vessels are patent and of good caliber.

At the outset we are faced with a difficult problem, for arteriosclerosis is a generalized disease and the prognosis for survival is limited. Barker[3] has reported that 54.6 per cent of persons treated for peripheral arteriosclerosis obliterans are dead of arteriosclerosis within three years of the time first seen. Pratt[13] states that occlusive vascular disease is the cause of death of 40 per cent of patients over forty years (60 per cent if the heart is included) and that 20 per cent of this group will lose part of or a whole member before death.

In patients with peripheral arteriosclerosis obliterans the effective arterial obstruction represents the sum of the organic obstruction and the constriction from associated vasospasm. The resultant manifestations are those of diminished skin circulation, manifest by lowered temperature, cyanosis, ulcers or gangrene, and those of disminished muscle circulation manifest by intermitten claudication and rest pain. Sudden onset of more severe symptoms in the limb results from thrombosis of diseased vessels. For example, the patient may have sudden severe pain in the calf of the leg which gradually disappears in a few days. This represents thrombosis of one of the small arteries supplying the muscles of the calf. More extensive thrombosis or thrombosis of more critical vessels such as the digital arteries may lead to gangrene.

Some physiologic studies have indicated that sympathectomy increases the circulation of the skin and not that of the muscle.[1,9,17] However, more recent studies indicate that there probably

---

Read before the Saint Paul Surgical Society, March 19, 1952.

is increase of circulation to both skin and to the muscle. After sympathectomy there is a very marked increase of blood flow through the femoral artery. In the dog this amounts to almost twice the normal blood flow. Popoff[12] and others have studied the arteriovenous shunts in the normal limb circulation and feel that there may be danger of releasing the constricting tone on these shunts in a limb with seriously impaired circulation. The added shunting of blood through these arteriovenous channels made patent by sympathectomy could deprive the distal parts of enough blood to cause gangrene. Cases of gangrene following sympathectomy have been reported by Atlas,[4] Freeman[7] and others. These cases have been in patients with low vasomotor tone (i.e., little associated vasospasm) as evidenced by the fact that they showed no response to sympathetic block. Two factors which must be considered in evaluating such post-sympathectomy gangrene are (1) a fall in blood pressure during operation, which would favor the development of thrombosis in the severely compromised vessels, and (2) trauma to the aorta by retractors, with fracture of an arteriosclerotic plaque and plugging of a distal vessel by a fragment of the plaque.

Evidences of arteriosclerosis obliterans obtained by history can be listed as follows: coldness, numbness, paresthesis, pain at rest and intermittent claudication.

Evidences of arteriosclerosis obliterans found upon physical examination are:

1. Color changes:
    Pallor on elevation
    Rubor on dependency
2. Loss of hair
3. Atrophy of the skin and muscles
4. Temperature changes
5. Impairment of sensation
6. Lack of pulsations:
    Dorsal pedal, posterior tibial, popliteal, femoral, aortic
7. Ulcers and gangrene

Further information as to the state of the circulation can be gathered by special tests. The simplest of these is oscillometry, done with an instrument such as the Collens sphygmo-oscillometer. With this instrument, which is read in points of oscillometric index, one obtains indication of the pulsatile blood flow of the limb. Procaine lumbar sympathetic block is perhaps the most valuable test, for it gives a reasonably good evaluation of what can be expected from sympathectomy. Warming of the extremity and relief of pain reveals the presence of considerable vasospasm and indicates that a good result can be expected. However, some patients with arteriosclerosis obliterans will have a good result from sympathectomy in spite of failure to respond to sympathetic block as judged by skin temperature. The response to block is best determined by digital plethysmographic studies.[8] This has been shown to be more accurate than skin temperature studies, for it records the volume of blood and not the temperature of the blood. The temperature of the blood may be considerably lowered in the distal vessels of diseased extremities.

Arteriography is valuable where the disease is localized and can be attacked directly. The procedure, in certain instances, gives valuable information.

Sympathectomy was first undertaken by Leriche[10] in 1917 in spastic arterial disease. His technique was a periarterial sympathectomy, but in 1924 Royle[15] first noted the effect of lumbar sympathectomy on the limb. Brown[5] in 1926 reported the first cases of sympathectomy in Buerger's disease, and in 1932 Brown and Adson[2] published a more extensive study of sympathectomy in this disease.

The prime argument for sympathectomy is the relief of the vasospasm which is associated with arteriosclerosis obliterans. Rector[14] found that 88 per cent of patients with low vasomotor tone developed adequate collateral circulation after arterial occlusion, while in only 34 per cent of those with high vasomotor tone did adequate circulation develop without sympathectomy.

The main criteria for sympathectomy in this disease is the presence of a cold, moist foot having decreased pulses. A good response to sympathetic block is desirable. The foot which is not apt to benefit is the cold, waxy, dry foot with considerable sensory deficit which develops intense cyanosis upon dependency. Likewise, the foot with well-developed gangrene and edema ordinarily responds poorly to sympathectomy. On the other hand it is advisable much of the time to attempt sympathectomy in the doubtful cases, for if amputation is necessary, there may be sufficient improvement of circulation following the operation to allow for local amputation or better healing of a major amputation stump.

The sympathectomized limb is warm and dry;

it warms faster and cools more slowly than the normal limb. It is not affected by reflexes or emotions.

The use of vasodilator drugs such as priscolene, roniacol, paveril phosphate, dihydroergocornine and others, is not as satisfactory as sympathectomy, for their effect is general and thus cannot be of as much benefit to the limb as an operation which promotes local vasodilatation. All patients with obliterative vascular disease should discontinue the use of tobacco if they wish to benefit from any type of treatment.

Technique of Operation

The patient is placed on the operating table supported by rolls so that he lies halfway between the lateral and supine positions. The table is broken and the kidney rest raised. The incision begins at the lateral border of the rectus and extends laterally for 3 inches in a transverse direction at the level of a line drawn from the tip of the twelfth rib through the umbilicus. The external oblique muscle fibers are cut, and the fibers of the internal oblique and transversus abdominus muscles are separated. The transversalis fascia is incised at the posterior angle of the wound in order to prevent entering the peritoneal cavity. The peritoneum is displaced anteriorly, the psoas muscle is exposed and dissection is carried down to the lumbar vertebrae anterior to the psoas muscle. The ureter is displaced with the peritoneum and care should be exercised to avoid injuring this structure. The lumbar sympathetic chain is identified,[11] and the second and third ganglia are removed after division of afferent and efferent rami. Care is taken to avoid injury to lumbar arteries and veins, for bleeding from these vessels can be troublesome. After removal of ganglia and the intervening chain the area is inspected for aberrant sympathetic nerve tissue,[16] hemostasis is assured, and the peritoneum is allowed to fall back in place. Closure of the wound is effected in layers.

In general, we prefer spinal anesthesia, but also use pentothal-curare and local anesthesia. Ether is not used, for it tends to cause vasoconstriction in the diseased extremity.[6] Local anesthesia has proved to be valuable in the poor risk patient and is used either by local infiltration technique or as a nerve block.

The completeness of the sympathectomy can be nicely demonstrated postoperatively by starch-iodine sweating tests. This gives accurate information regarding the extent of denervation accomplished by the sympathectomy.

A group of fifty unselected cases of peripheral arteriosclerosis obliterans has been studied for this presentation. The average age was 56.8 years, the range being from thirty-three to seventy-six years. Thirteen (26 per cent) were diabetics. The presenting symptoms and signs are tabulated as follows:

Symptoms	*No. of Patients*	*Percentage*
Claudication	42	84
Coldness	41	82
Rest pain	40	80
Pallor	39	78
Rubor	38	76
Pregangrene	17	34
Gangrene	9	18

Unilateral sympathectomy was carried out in twenty-nine cases and bilateral sympathectomy in twenty-one cases. Claudication was improved in 64 per cent, coldness was improved in 87 per cent, and rest pain was relieved in 95 per cent.

Results	*No. of Patients*	*Percentage*
Good	37	74
Fair	8	16
Poor	5	10
Group with Gangrene:		
Improved	4	
Major amputation	2	
Toe amputation	3	
Group with Pregangrene:		
Improved	11	
Major amputation	3	
Toe amputation	3	

Of the five poor results, four showed no response to sympathetic block. Two of the four underwent major amputation three months later, one two months later, and one eleven days after sympathectomy.

One patient entered the hospital after an acute popliteal thrombosis. Sympathectomy was done the same day. Seven days later acute popliteal thrombosis developed on the opposite side. Major limb amputations were necessary thirteen and nine days, respectively, after the sympathectomies. The patient developed cerebrovascular thrombosis and died two weeks after the last amputation.

It is felt that the sympathectomy did not hasten the gangrene in this case.

Conclusion

Sympathectomy has had a beneficial effect in improving circulation of extremities imperiled by obliterative arteriosclerosis. It has relieved rest pain, improved intermittent claudication, relieved coldness and dampness. We believe gangrene has been averted in some cases, and in other cases it has allowed amputation at a lower level than could have been undertaken in the unsympathectomized limb and a better stump has been obtained for wearing a prosthesis.

In addition to the group of patients here recorded, sympathectomy has been employed in patients who have had previous amputation for vascular deficiency. The sympathectomy in most cases has been done on the opposite side to protect the remaining extremity which is subjected to additional trauma in walking. In other cases sympathectomy has been carried out on the already amputated side to improve the condition of the stump for use of a prosthesis.

Summary

1. The use of sympathectomy in peripheral arteriosclerosis obliterans has been discussed.

2. Fifty cases of lumbar sympathectomy have been reported and the effect of the operation on the arteriosclerotic extremity has been recorded.

3. The final conclusion of this study is that sympathectomy has proved to be beneficial in the treatment of this disease.

DETECTION OF TUBERCULOSIS

The primary responsibility for the detection of tuberculosis rests to a great extent with the practicing physician. He is primarily responsible for the early detection of this disease in those patients who present themselves to him with symptoms and in those patients who present themselves to him for obstetric care. He is also primarily responsible for guidance where tuberculosis is detected in admissions to general hospitals for the treatment of some other condition. In addition to the primary responsibility for the detection of this disease in those patients who are directly under his care, the practicing physician also has a partial responsibility in the diagnosis and detection of tuberculosis in apparently healthy individuals in his community. Public health education on his part can be of tremendous value in the detection of early non-symptomatic tuberculosis. Tuberculosis is a disease of the family and community as well as the individual. The effect upon the social pattern and the physical well-being of the patient and his family is often great, resulting in extensive alteration of the pattern of life.—James M. Blake, M.D., *New York State Journal of Medicine,* February 1, 1952.

HUMAN LEPTOSPIROSIS DUE TO LEPTOSPIRA POMONA

Report of First Case in Minnesota

WESLEY W. SPINK, M.D.
Minneapolis, Minnesota

ELSEWHERE[12] attention has been called to the difficulty of distinguishing infectious mononucleosis from acute brucellosis. It was pointed out that both of these diseases may display a similar clinical pattern; both may reveal the same hematologic findings, especially with relation to the presence of atypical lymphocytes; and both may exhibit an elevated heterophile antibody titer. The following case report of leptospirosis closely simulated infectious mononucleosis and acute brucellosis in several respects and only as a result of serologic tests was the precise nature of the illness defined. The case is of further interest because it represents the first instance in Minnesota of recognized leptospirosis due to *Leptospira pomona,* or a closely related species.

Many human cases of leptospirosis with and without jaundice have been recognized in the United States as being due to *Leptospira icterohaemorrhagiae* or *Leptospira canicola.* The former as the cause of Weil's disease has its reservoir in rats and the latter in dogs. Although human leptospirosis caused by the species *L. pomona* has been recognized in Australia, Europe and other parts of the world as a common cause of a febrile disease with serous or benign lymphocytic meningitis, very few cases have been reported in the United States. As will be pointed out shortly, this species of leptospira probably has an extensive reservoir in this country, and the disease is very likely being overlooked. Only very recently has evidence been presented by Beeson and his associates[1] from Georgia that human leptospirosis due to *L. pomona* existed in the United States. Shortly thereafter Schaeffer[11] investigated an epidemic of leptospiral meningitis that occurred in Alabama and concluded that 18 of 22 individuals had serologic evidence of an infection due to *L. pomona.* And more recently Coffey and his group[3] in Texas have reported an instance of leptospirosis probably due to this species.

My interest in the possibilities of this type of leptospirosis existing in Minnesota was stimulated by the foregoing reports and also by personal observations made in Europe during the summer of 1951. Many patients with leptospiral meningitis due to *L. pomona* were seen in the Fever Hospital at Rijeka (Fiume), Yugoslavia, with the Director, Dr. H. Rukavina. The cases represented young adults from rural areas who had had contact with the reservoir in swine. For this reason, the disease is commonly known as "swineherd's disease" or "maladies des porchers." Then an opportunity presented itself to spend several days in Switzerland with Dr. O. Gsell, who has had an extensive clinical experience with leptospirosis, especially with cases due to *L. pomona.* His observations have just been documented in an excellent monograph on leptospirosis.[7]

Case Report

C. D., twenty-three years old, a single white man, was employed in a meat-packing plant and was first seen on February 13, 1952. He had been in good health until February 8. While at work he "felt uneasy" with pains in the back, shoulders, arms and joints. Toward evening he developed chills, fever, weakness and profuse sweats. During the night and the following day he acquired a severe headache. His temperature was 104° F. He became anorexic, which was associated with abdominal cramps and vomiting. Insomnia appeared. The severe headaches, fever, anorexia and weakness persisted until February 12. On February 13, or on the sixth day of his illness, his temperature was normal, but he felt weak and he had lost 10 pounds in weight during this period. Upon further interrogation he stated that he had always enjoyed good health. In recent years he had served three years in the Air Force without being ill. Coincident with the patient's illness his father was at home with a "virus pneumonia." The patient had been working in a meat-packing plant for four years doing odd jobs around the hog kill. For the six months prior to his present illness he had been removing the intestines from freshly killed hogs.

Physical examination revealed a well developed and well nourished young male who appeared ill. His temperature was 97.4 F., pulse, 76, and blood pressure, 115/60. His skin was dry. There was no evidence of icterus. There was no rigidity of the neck. The only abnormal finding was a moderate enlargement of the lymph nodes in both axillae, which were slightly tender on palpation. The spleen was not palpable.

From the Department of Internal Medicine, University of Minnesota Hospitals and Medical School, Minneapolis, Minnesota.

Presented before the Minnesota Society of Internal Medicine, Duluth, Minnesota, May 17, 1952.

TABLE I. AGGLUTININ TITER OF ACUTE AND CONVALESCENT SERA FROM PATIENT AGAINST THREE SPECIES OF LEPTOSPIRA.

Date Serum Obtained from Patient	Day of Disease	Titer of Agglutinins		
		L. ictero	L. canicola	L. pomona
2-13-52	6	0	1:116	0
2-15-52	8 (meningitis)	0	1:256 (incomplete)	1:128 (complete)
2-23-52	16	1:128 (incomplete)	1:1024 (incomplete)	1:4000 (complete)
3-8-52	30	1:128 (incomplete)	1:512 (incomplete)	1:2000 (complete)
3-30-52	52	1:64	1:128	1:2048

TABLE II. RESULTS OF LIVER FUNCTION TESTS ON PATIENT'S SERA

Date of Serum	Day of Illness	Cephalin Flocculation	Zinc Turbidity (Normal 0 to 3 units)
2-15-52	8	3÷	4
2-23-52	16	2÷	12
3-8-52	30	3÷	9

The results of laboratory procedures performed on February 13, or the sixth day of his illness, were as follows: Urine—slightly cloudy and amber in appearance; specific gravity, 1.026; 1+ albumin; sediment showed 3 to 4 leukocytes, 6 to 8 erythrocytes, and 1 cellular cast per high power field. Blood—hemoglobin, 14.1 grams; 7,450 leukocytes with 48% neutrophiles, 33% lymphocytes, 15% monocytes, 1% eosinophiles, 2% basophiles and 1% plasma cells. The erythrocyte sedimentation rate (Westergren) was 41 mm. in one hour. Agglutinins for brucella were present in a titer of 1 to 40. The heterophil antibody titer was 1 to 112, and 1 to 56 after absorption of the serum with guinea pig kidney. A culture of blood for brucella remained sterile. A serologic test for syphilis was negative.

The impression after this initial examination was that the patient had acute brucellosis. Previous experience with employes from the hog kill of the same packing plant had presented the same epidemiologic information with a similar clinical picture and the diagnosis had been proved bacteriologically in several cases. Since we have become more cognizant of the similarity in the clinical, hematologic and serologic findings in patients with infectious mononucleosis and brucellosis, serologic studies for both diseases were carried out, and a blood film was reviewed by Dr. Dorothy Sundberg. She remarked that the neutrophils appeared toxic and contained Döhle bodies. Many of the lymphocytes showed leukocytoid alterations, most of which could be classified as Type I lymphocytes of Downey. The hematologic picture was compatible with either brucellosis or infectious mononucleosis. Because the patient was afebrile he was referred back to his physician, Dr. D. L. Donovan of Albert Lea, Minnesota, for further observation.

Within forty-eight hours the patient had a recurrence of fever and headache, and evidence of meningitis was established by Dr. Donovan on February 15, which was the eighth day of illness. At this time laboratory data revealed the following: urine was normal. The hemoglobin was 12.6 grams; the leukocyte count was 8100 with 59% neutrophiles, 34% lymphocytes and 7% monocytes. Brucella agglutinins were still present in a titer of 1 to 40, and the heterophil antibody titer was 1 to 112. A lumbar puncture was carried out. The cerebrospinal fluid was under normal pressure. There were 92 cells present, all of which were lymphocytes. The protein was 22 mgs. per cent, and the sugar 62 mgs. per cent. While the clinical picture was still compatible with acute brucellosis or infectious mononucleosis, the possibility of leptospirosis due to *L. pomona* was now entertained. Shortly after this episode of meningeal irritation the patient recovered and returned to work. Two months later, when this report was prepared, he was in good health.

Through the co-operation of Dr. Martin Frobisher, Jr., and Dr. Martha K. Ward of the Communicable Disease Center of the U. S. Public Health Service, Chamblee, Georgia, several specimens of sera were examined serologically for leptospirosis. The results are presented in Table I. Agglutinins were demonstrated for *L. icterohaemorrhagiae, L. canicola* and *L. pomona*, but not for *L. grippo typhosa* or *L. bataviae*. In submitting this report of the results Dr. Ward stated, "Although the titers vs. the *L. canicola* antigen were higher than *L. pomona* in the two early sera, the later much higher rise in titer vs. *L. pomona* and also the much more complete agglutination of this antigen would indicate an infection with *L. pomona* or closely related type." It is also to be noted in Table I that a high titer for *L. pomona* persisted, whereas the titers for the other two species had decreased to much lower levels.

Agglutination tests for brucella performed with each of the specimens of serum showed a titer of 1 to 40. This indicated probably exposure to the disease in the past rather than active brucellosis, a conclusion based upon other observations carried out in this clinic.[10,13] Although the patient was not icteric and displayed no other clinical evidence of hepatic dysfunction, two tests for liver function gave abnormal results with the patient's sera as shown in Table II.

Discussion

While it is now known that several different species of leptospira may cause human disease, only the three species, *L. icterohaemorrhagiae, L. canicola* and *L. pomona* have thus far been implicated in the United States. A recent communication indicates that so-called Fort Bragg fever thought to be of viral origin is due to another species of leptospira, *Leptospira autumnalis,* known to be a cause of human leptospirosis, but not previously associated with disease in this country.[5] Because there is evidence that infections due to *L. pomona* will assume increasing attention in this country brief reference will be made to some of the epidemiologic and clinical features of disease due to this species. The original strain of *L. pomona* was isolated from the blood of a dairy farmer who had a mild type of febrile illness and who lived in Pomona, which is a community just north of Brisbane, Australia.[2] Within the next five years 80 human cases were recognized in this area.[4] Agglutinins for *L. pomona* were also demonstrated in the sera of cattle and hogs, and the organism was isolated from a hog.[9] The same species was next isolated in Italy, and in 1944 and 1945 Gsell proved that the disease known since 1933 in Switzerland, Savoy and Northern Italy as "maladie des porchers" or swineherd's disease was caused by *L. pomona.*[14] Gsell[7] also established that the reservoir of the disease was in hogs, and but rarely in the dog or cat. Some interesting observations have been made in the United States relative to the reservoir of *L. pomona.* There is a baffling disease of horses known as recurrent iridocyclitis or periodic ophthalmia. Heusser[8] in Europe found a high incidence of leptospiral agglutinins for *L. pomona* in afflicted horses as compared to the low number in normal horses. While the organism remains to be isolated the serologic observations of Heusser in horses have been confirmed in the United States by the group in the Veterinary Division of the Army Medical Department of Research.[15] Another provocative epidemiologic feature arising in this country is the finding that isolated strains of bovine leptospira known as New Jersey C164 and New York A are indistinguishable from *L. pomona.*[6] That *L. pomona* is probably endemic in domestic animals in this country is reflected in a recent report that I received from Dr. R. V. Johnston of Indiana. His group in co-operation with the Veterinary Division of the Army Medical School has isolated and identified a strain of *L. pomona* from swine in Ohio. On the farm from which this strain was acquired, the following results of serologic tests were obtained: agglutinins for *L. pomona* were present in 53% of 52 hogs, in 80% of 18 cattle, in 100% of 2 horses, 0% of 2 dogs and 0% of 2 rats. It is to be recalled that following the human epidemic in Alabama, Schaeffer[11] observed agglutinins for *L. pomona* in hogs, horses and mules, but an extensive rat survey failed to yield either cultures or agglutinins for *L. pomona.* A recent communication from Dr. Charles J. York of the Veterinary Virus Research Institute of the New York State Veterinary College, Ithaca, New York, stated that the distribution of *L. pomona* in swine and cattle is probably very widespread in the United States.

Except for the possible ocular lesions in horses and the disease in swine little is known concerning the manifestations of the disease in animals. According to Gsell,[7] infected pigs display gastro-intestinal disturbances with anorexia; they turn round and round, and manifest inability to stand up; and then rigidity and spasm appear. The disease seldom results in death, and lasts about two weeks or less.

Gsell[7] has detailed the manifestations of the human disease in 217 cases, but only the essential features will be presented here. In the Swiss cases, over 90 per cent of the cases occurred in males, and the age incidence was between 20 and 29 years. The disease has a prodromata of one to two days of malaise and headache, and then there is the abrupt onset of chills, fever, weakness to a point of physical collapse, and severe headache. A high fever of the plateau type lasts for three to six days and then there is a remission for one to two days followed by a second rise of temperature for a few days, and then recovery. In about 60 per cent of the cases, conjunctivitis appeared during the first rise of fever. Meningismus appears during the first peak of fever, but the signs of meningitis are particularly prominent during the second rise. Icterus is extremely rare. In about 10 per cent of the cases there was a skin eruption consisting of morbilliform and urticarial lesions, and restricted to the trunk. Renal irritation is manifested by the temporary presence of albuminuria and occasional erythrocytes and leukocytes. There is a tendency to leukopenia with neutrophilia during the first week, and a normal leukocyte count with relative lymphocytosis during the second week. The erythrocyte sedimentation rate is elevated, and the serum proteins show an elevation of globulins. During the first peak of fever, or phase I of the disease, the cerebrospinal fluid shows only an elevated pressure, but during the second rise, or phase II, there may be 50 to 200 cells. At first there is an equal cellular distribution between lymphocytes and neutrophiles, followed by a predominance of lymphocytes. The protein value of the spinal fluid is 40 to 80 mgs. with normal values for glucose and chlorides. Leptospira can be cultured from the cerebrospinal fluid during the first febrile phase, but not during the second phase. The diagnosis is established by isolation of *L. pomona* from the blood, cerebrospinal fluid or urine during the first week of illness. During the second week, greater reliance must be placed upon the agglutination titer. Gsell is of the opinion that the titer should be at least 1 to 400. Cross reactions do occur with the other species, especially *L. icterohaemorrhagiae* and *L. canicola,* though usually at a lower titer, and these antigens are usually incompletely agglutinated by the serum. Agglutinins also appear in the cerebrospinal fluid, though at a lower titer than found in blood. Fortunately, complications are rare. Iridocyclitis that may be delayed four to 12 months after illness may appear, and in Gsell's cases, this occurred in about 5 per cent of the cases. A post-infectious asthenia may persist in some cases. Recurrence of the disease is a rarity. Gsell[7] found that both aureomycin and terramycin were quite effective therapeutically during the first stage of the disease, but not during the second stage. The administration of 2 grams of either antibiotic daily for four to five days resulted in prompt improvement and prevented the second rise in fever.

From a review of the literature, and as a result of limited observations made in this country, it is apparent that the animal reservoir of *L. pomona* may be much more widespread than has been realized, and that leptospirosis caused by this species may occur quite frequently. The disease should be considered in those individuals with an unexplained febrile condition whose occupation brings them in close contact with farm animals. The possibility of leptospirosis should be entertained in every case of benign lymphocytic meningitis, and serum should be collected for serologic evaluation during the acute and convalescent stages of the illness. Since iridocyclitis is an occasional late complication, agglutinins for *L. pomona* should be carried out on the serum of patients having this condition. Other diseases from which cases of *L. pomona* should be differentiated include Q fever, brucellosis, infectious mononucleosis, and lymphocytic meningitis associated with mumps and the virus of lymphocytic choriomeningitis.

Summary

1. A young adult male employed on the hog kill of a meat-packing plant presented himself with an acute febrile illness that simulated acute brucellosis and infectious mononucleosis. Serologic studies demonstrated that the illness was due to *Leptospira pomona,* or a closely related species. This represents the first recognized case in Minnesota.

2. The reservoir of *L. pomona* is in cattle and swine, and the disease may be quite widespread in these animal species in the United States. The disease should be suspected in humans with an acute febrile disease associated with lymphocytic meningitis, especially in those having had contact with cattle or swine. The disease is of short duration; the prognosis good; and aureomycin or terramycin are effective therapeutic agents.

BLOOD GROUP FACTORS

Part I. Inheritance of the Blood Group Antigens

G. A. MATSON, Ph.D., and R. W. KOUCKY, M.D.
Minneapolis, Minnesota

IN THE past decade there has been a tremendous expansion of knowledge and stimulation of interest in the human blood groups. Initiated by the discovery of the Rh factor, this recent interest has been sustained both by the demand for safer transfusions and by the hope of finding a better understanding of the cause and treatment of hemolytic disease of the newborn. The large mass of rapidly accumulating data on the newly found blood groups is in the fields of genetics and immunology, which ordinarily are outside the training and experience of most physicians. It seems desirable therefore to review and bring together in a brief paper the essential data and interpretations in these subjects so that physicians can have them available for ready reference.

Genetic Terminology

Blood group antigens are hereditary and an understanding of a few of the geneticist's terms is indispensable in any study of these blood factors. "Chromosomes" are familiar to physicians as the rod-like bodies seen in the nucleus of cells undergoing mitosis. The chromosomes carry the determiners of individual inherited characteristics. A chromosome can be thought of as a string of beads in which each bead represents a "gene," the basic hereditary unit of the chromosome. Each gene is arranged in a linear order on the chromosome and each has its own specific position on the chromosome and this position is known as its "locus." Since, during the maturation of the spermatozoa and ova, chromosomes divide along a longitudinal plane, each gene must be paired in order to be properly represented in each half of the divided chromosome. In the matured spermatozoa and ova of the human, there are twenty-four single chromosomes which at fertilization combine to make up the twenty-four pairs of homologous chromosomes found in the nuclei of the somatic cells of the human body. Each hereditary blood antigen, therefore, is represented by a pair of genes standing side by side in a specific location (locus) on the chromosome. Genetically each blood group antigen behaves as a unit and is inherited as such. Serological tests for the specific blood group antigens are therefore indirect tests for the presence of specific genes.

TABLE I. BLOOD GROUP SYSTEMS

SYSTEM	LOCI	ALLELOMORPHS
ABO	1	A^1, A^2, B, O
Rh	3	1-C, C^w, C^u, c, c^v
		2-D, D^u, d
		3-E, e
MNS	1	M, N, S, s
Kell	1	K, k
P	1	P, (p, postulated)
Lutheran	1	Lu^a, (Lu^b, postulated)
Lewis	1	Le^a, Le^b
Duffy	1	Fy^a, (Fy^b, postulated)
Kidd	1	Jk^a, (Jk^b, postulated)
FAMILY TYPES		
Levay	1	Levay +, Levay —
Graydon	1	Gr +, Gr —
Jobbins	1	Jobbins +, Jobbins —

Genes sometimes undergo mutation. This involves some qualitative or quantiative change in one member of a pair of genes located on a chromosome pair. The new variant thus formed is known as an "allele" or "allelomorph." Some genes have developed many ("multiple") allelomorphs. Only one pair of allelomorphs can occur at one locus but if there are multiple alleles any two of these can make up the pair. These two allelomorphs made up of any possible combination is the specific "genotype" of that individual for that one blood group. If the two allelomorphs in the pair are identical the genotype is "homozygous." If the two allelomorphs are different, the genotype is spoken of as "heterozygous."

Blood Group Systems

All of the allelomorphs of any one blood group gene are carried on one chromosome and this family of alleles is known as a blood group "system." Each of the blood group systems is carried on a different chromosome. Two systems do not appear in one chromosome.

Table I lists the important blood group systems.

Most of these systems can be involved in transfusion reactions or erythroblastosis; in fact, many of the newer blood groups have been identified

---

Dr. Matson is Director of the Minneapolis War Memorial Blood Bank and Dr. Koucky is Medical Executive.

through study of reactions or maternal sensitization. The ABO system identified by Landsteiner[10] in 1900 is by far the most important and has served as the basis for all transfusion work for the past fifty years. The system, like that of most of the blood groups, is carried within one gene. There are 4 common allelomorphs within the ABO system known as A_1, A_2, B and O. The genotypes possible from these four allelomorphs are expressed as ten allelomorphic pairs, A_1A_1, A_1A_2, A_2A_2, A_1B, A_2B, A_1O, A_2O, BB, BO, OO. Of these, A_1A_1, A_2A_2, BB and OO are homozygous whereas the others are heterozygous. Two more allelomorphs known as A_3 and A_4 have been described but these are rare. It is customary in ordinary routine transfusion work to refer to the four blood groups only as O, A, B and AB. It sometimes happens that an A individual of one subgroup becomes sensitized by transfusion to the other subgroup of A. In such cases it is important that blood of the homologous A subgroup be used for transfusion. In paternity exclusion studies it is often important to test for subtypes of A and in genetics and heredity studies the full genotype formula is conscientiously sought.

The M substance of the MNSs system was first described by Landsteiner and Levine[11] in 1927 and since that time the four allelomorphs MNSs have been identified.[12,26,27] Numerous examples of sensitization to these factors have been observed.[1,7,19,28] Race and Sanger,[25] for example, identified 9 instances of M sensitization in their own work.

The P factor was also identified in 1927 by Landsteiner and Levine.[12] Sensitization to the P substance may be quite common but if so, the antibodies formed are weak and usually the reactions are not severe enough to cause clinically apparent reactions.

In 1946, the Lutheran,[2] Kell[3] and Lewis[20] factors were described. In 1950, the Duffy factor[4,5] was added and more recently the Kidd factor[21] was discovered. Each of these blood substances has been named for the patient originally studied.

The Kell-positive factor is indicated by K and the Kell-negative as k. However, the terms in case of the Lutheran, Lewis, Duffy and Kidd factors do not follow this pattern. By the time these factors were discovered, the difficulties and confusion resulting from prior methods of terminology were already apparent. If K were used for Kell it could not be used for Kidd; if L were used for Lutheran, it could not be used for Lewis. D or D^u already used for allelomorphs in the Rh system, could not be used for Duffy. Therefore, the terms as given in the table were adopted. Furthermore, the terms "large D" and "little d" are distinctly cumbersome and in the more recently discovered blood factors, the use of superscript "a" for one allele, and superscript "b" for the next identified has been started. This system permits the labeling of other alleles as c, d, e, and so on if such should be identified in the future. This indicates the tendency to discard the terms "positive" and "negative." Perhaps soon there will be a standardization of all the terms used in this field.

Each year is producing more evidence that these factors are occasional causes of significant transfusion reactions or of erythroblastosis. The frequency of sensitization, however, is small and these factors need not be routinely investigated in ordinary transfusion work. However, these blood factors and the newer Rh allelomorphs must be investigated in cases of unexplained reactions to blood or in cases of erythroblastosis not identified with the usual antigenic incompatibilities.

The so-called "family" type of blood factors—the Levay,[2] Graydon,[9] Jobbins[8] and others—are of little clinical importance. Here again the blood antigens were named for the patients in whom the factors were discovered, or the investigator. These rare blood factors appear only in members of the particular family group and not in unrelated individuals. They are of interest primarily because they are mutations having a strikingly narrow distribution in the population. These blood factors have caused sensitization but only in isolated instances.

More recently Levine et al[14] have described another blood group factor, Jay, which was present in certain tumor cells. Their unexpected findings led them to the conclusion that a blood factor in tumor cells may arise from a genetic mutation.

The Rh-Hr System

Discovery of the Rh system of blood factors unquestionably has been the greatest contribution to blood transfusion knowledge since the identification of the ABO system by Landsteiner at the turn of the century. The system, unfortunately, is very complex because it is carried on three separate genes and these have undergone considerable mutation with the production of many allelomorphs.

The allelomorph which we now know as $R(Rh_0)$ was the first one discovered.[13,15] At the time of these first studies there was no conception of the complexity of the system. It was thought that this factor was present in certain individuals and these people were therefore called Rh positive. Those individuals in whom the element was absent were called rh negative. Soon it became apparent that this was only a partial truth. It was realized that while the rh negative person did not have the Rh factor, he did have in its stead a factor which, because it occurred on the red blood cells reciprocally when Rh was absent, came to be known as the Hr factor.[16] It quickly became apparent that there must be at least three Rh-Hr combinations.[17,22,23,24] Fisher[6] quite sensibly named the three new factors C, D, and E, following up the A and B terminology selected by Landsteiner. The three Rh "positive" factors are now known by the large letters C, D, and E. The corresponding reciprocal Hr or rh "negative" factors are designated by the small letters c, d, and e. The three Rh-Hr or as commonly stated now the C-c, D-d, and E-e factors are each represented by a pair of genes occurring at adjacent but different loci on the chromosome. The C-c and D-d genes are known to have undergone further mutation with the production of other allelomorphs.

Table I lists the three genes of the Rh system and the known allelomorphs of each. The number of the Rh genotypes possible from this large number of allelomorphs is very great. Even without considering the recently discovered allelomorphs, C^w, C^u, c^v and D^u, there are 78 genotypes. The genotype is complex because all three loci in each of the paired genes must be expressed. In a single locus system like the ABO, the genotype is represented by only one letter for each member of the pair of genes, i.e., A/A, A/B, or A/O, etc. But in case of the Rh system which is a three locus system the genotype includes three letters on each side, i.e., CDE/CDE.

The various combinations of allelomorphs forming the genotypes do not occur in even proportions. Only a few occur frequently and the great majority are rare.

Table II lists twelve of the Rh groups defined by the four anti-sera Anti-C-c-D-E.

TABLE II. RESULTS OF TESTS OF BLOOD FROM AMERICAN WHITES[18]. 335 RANDOM SAMPLES

Genotypes	Percentage
Common	
CDe/cde	30.76
CDe/CDe	19.09
cDE/cde	16.72
CDe/cdE	14.63
cde/cde	14.03
Rare	
cDe/cde	2.69
cdE/cde	1.19
Cde/cde	0.87
Cde/cdE	0.00
Cde/Cde	0.00
CDe/CDE	0.00
CdE/Cde	0.00

The results shown in Table II indicate that the Rh groups Cde/cdE, Cde/Cde, CDe/CDE, and CdE/Cde are rare in American white people, not having been found in the 335 which were studied by Levine at random. In this study, the anti-C serum used contained also anti-C^w. The more recently discovered allelomorphs C^u, D^u and c^v were not identified in this study. Antisera against the allelomorph d is not yet available commercially and for the time being the presence of the d antigen when it occurs with D cannot be determined directly and therefore must be arrived at through family studies or must necessarily be presumptive based on the statistical probability as given in Table II. By the method of calculating from known gene frequencies, there is less than a 6 per cent error in distinguishing the homozygous -D-/-D- from the heterozygous -D-/-d-.

The common usage of terms is illustrated as follows: The Rh genotype CDE/CDE is Rh positive for all three specificities and is homozygous. The genotype CDE/cde is Rh positive for all specificities and is heterozygous for all. Taking the three most common genotypes (Table II), as examples, CDe/cde is Rh positive for C and D and rh negative for E and is heterozygous except for e. CDe/CDe/ is the same except this pattern is homozygous throughout. cde/cde is rh negative for all three specificities and is homozygous.

The Rh serum recommended for routine obstetrical work for screening positive and negative patients is the anti-D serum. Individuals negative to this serum are -d-/-d- and reference to

Table II shows that their complete genotype is likely to be cde/cde. It must be pointed out that 2 per cent of these individuals negative to anti-D serum will be positive to C or E. The significance of this in transfusion work will be discussed in Part II.

TABLE III.
EQUIVALENT
NOMENCLATURE
OF Rh SYSTEM

Weiner Method	Fisher Method
Rh$_0$	D
rh′	C
rh″	E
rh′ rh″	CE
Rh$_1$	CD
Rh$_2$	DE
Rh$_1$, Rh$_2$	CDE
Hr$_0$	d
hr′	c
hr″	e

As will be discussed later, determination of the father's genotype is of help to the physician. The frequency of genotypes listed in Table II applies to males as well as females. From the table, it can be seen that the heterozygous combination -D-/cde occurs in approximately 45 per cent of all Rh positive white population. When the husbands of rh negative women are heterozygous (i.e., they carry the rh negative factor) then on the average 50 per cent of their offspring will be rh negative. The genotype -D-/-D- occurs in about 35 per cent of all Rh positive fathers. These men are homozygous to the D factor and all of their children will be (D) Rh positive.

The Fisher CDE system of nomenclature is not universally accepted. Weiner prefers a system which he has devised and in America this is used to some extent. The system probably is of value to some individuals but in general, clinicians find it rather cumbersome. The equivalent terms in the Weiner and Fisher system of nomenclature are given in Table III.

Summary

Blood cells possess specific inherited characteristics. These characteristics have undergone mutations so that some of the characteristics now are represented by a sizable family of variants. A specific blood cell characteristic and its variants is known as a blood group system. The two most important systems are the ABO and the Rh-Hr systems. The MN, Kell, Duffy, Lutheran, Lewis and Kidd factors are other blood group systems.

The ABO system is a simple one located within one gene. There are three major variants or allelomorphs and these three form the basis for the division of blood into the four major blood groups: AB, A, B and O.

The Rh system is much more complex because it is carried on three genes. It is recommended that the three genes be called C, D, and E, which can be conveniently spoken of as the three specificities of the Rh factor. Each gene has two major variants or allelomorphs designated as C and c, D and d, and E and e. The allelomorphs which are known as Rh positive are expressed by the large letters, C, D, and E. The allelomorphs which are called rh negative are expressed by the small letters, c, d, and e. Other allelomorphs have been discovered and these have been called C^w, C^u, c^v and D^u. These newer allelomorphs in the Rh system and other recently discovered blood factors such as Kell, Lutheran, Lewis, Duffy, Kidd are occasionally implicated as the cause of transfusion reactions or of erythroblastosis.

Since genes necessarily must be paired (in order to provide equal representations in each half of the dividing chromosome of the ovum and sperm), the complete Rh pattern or genotype is represented by six letters, for example, CDe/cde. In this example the individual is Rh positive to the C and D specificity and is rh negative to the E. He is heterozygous to the C and D and is homozygous to the e.

The commonly used Rh serum is anti-D serum. Therefore, the individual who is rh negative to this serum is -d-/-d- and from the table of frequencies it can be seen that most often the complete genotype must be cde/cde. However, in about 2 per cent of the white population blood negative to anti-D serum (-d-/-d-) can be positive to the C or E or both. The significance of this will be discussed in Part II of this paper.

The designations of genotypes by various modifications of the term Rh such as Rh$_o$, rh′ rh″, R$_1$, et cetera, seem to be too cumbersome for clinical use.

(Part II, Rh Sensitization, will appear in the July number.)

CIVILIAN CASUALTIES

Nearly two million casualties, the worst automobile accident toll in the nation's history, were recorded in 1951, according to figures recently released by The Travelers Insurance Companies.

Last year's traffic deaths totaled 37,100, an increase of 1600 over the 1950 mark. The injury count soared to 1,962,600, more than 160,000 over 1950, the Hartford firm reported.

The death and injury totals are highlight statistics from "Lucky You," eighteenth in the annual series of traffic accident data booklets published by The Travelers. The company collects and analyzes accident statistics from each state.

More than 13,000 persons were killed and 570,000 injured last year by drivers who were exceeding the speed limit, according to the report. Excessive speed was "far and away the most dangerous mistake in driving" in 1951.

More than 11,000 drivers under 25 years old were involved in fatal accidents and 416,000 more in personal injury accidents, the figures reveal.

Pedestrian experience in 1951 is termed "an island of encouragement in last year's ocean of accidents." A comparison of 1951 with 1950 shows that pedestrian deaths were "held in check" while injuries were reduced by nearly 9,000.

Other facts from "Lucky You":

Saturday was the most dangerous day of the week to drive.

More persons lost their lives during the hour from six to seven p.m. than in any other hour. Injuries hit their peak two hours earlier, from four to five p.m.

Ninety per cent of drivers involved in 1951 accidents were males.

Ninety-seven per cent of drivers involved in 1951 accidents had at least one year of experience behind the wheel.

Thirty-eight per cent of last year's fatal accidents occurred on the open highway.

There were 92 per cent more fatal accidents on icy roads last year than in 1950.—Public Information Department, The Travelers, Hartford, Connecticut.

THE NATURE OF PAIN

HAROLD G. WOLFF, M.D., JAMES D. HARDY, Ph.D., and HELEN GOODELL, B.S.
New York, New York

SENSATION constitutes an awareness of stimulation and bears a highly predictable relation to the intensity of the stimulus. Pain is no different from other sensations in this regard. It does differ, aside from its qualitative features, in that the adequate stimulus for pain sensation is the damaging of tissue. Perception may be viewed as the awareness of stimulation and considered as sensation with concomitant associations and reactions. The average level of stimulus at which pain sensation is first recognized is predictable and can be appraised quite apart from its associated meaning to the individual. Throughout this presentation, emphasis has been placed upon the need to deal separately with the effects of noxious stimulation leading to (a) adjustments without giving rise to sensation, (b) the sensation of pain, and (c) adaptations to pain *per se*. Taken together, they include perception, feeling states, moods and a variety of bodily reactions and behavior patterns.

The Adequate Stimulus

The initiating event for neural impulses involved in pain is the damaging of tissue, and is termed "noxious stimulation." Tissue damage, then, often extremely slight and completely reversible, becomes the keystone of the type of adjustments, sensations, feeling states, and behavior that constitute the pain experience.

The degree of stress which a given human tissue can withstand without being damaged is, under known conditions, uniform. The means of damaging tissue as a factor in such a generalization is a fundamental consideration since there must be a demonstrably close relationship between the energy applied and the rate at which damage is done.

The Dimensions of Pain

Pain sensation is readily recognized and appreciated as different from other sensations. There are several measurable dimensions of pain sensation considered under the following headings: quality—pricking, burning, aching; intensity —threshold to 10½ dols; extension, having to do with site, localization (circumscribed or diffuse), area and volume; and temporal aspects (duration, intermittency, rhythmic, pulsatile, seasonal, diurnal). Anatomically pain is considered in two categories: superficial, with identifiable qualities as pricking and burning and aching, with itching as a variation and combination of the first two qualities; and deep pain, with aching as the most prominent quality. Burning pain sensations may also arise from deep tissues, as for instance, from the esophagus and stomach, or bone marrow.

When pain is analyzed for the purpose of identifying the organ or part involved, additional definition is gained by considering its modifiability, i.e. what causes the pain to increase or to decrease. To the precise identification of the structures responsible for pain, observations of concurrent motor and vasomotor effects are pertinent.

The sensation of pain has a lowest intensity, the threshold pain, and a maximum intensity beyond which no further discriminations of intensity can be made. There are a limited number of just noticeable differences in pain intensity, approximately twenty-one from threshold to maximum. An intensity of pain has been elaborated, using the word "dol" to indicate two steps in discrimination of intensity. Pain intensity is determined by the intensity of noxious stimulation, although modification of pain intensity can occur in areas of hyperalgesia. Furthermore, zones in which painful stimuli are perceived as more than usually intense do not necessarily have lowered pain thresholds. Indeed, two categories of hyperalgesia can be defined: one ("primary") in which the pain threshold is appreciably lowered, occurs with tissue damage; and the second ("secondary") in which the pain threshold is unaltered but due to alterations in the excitatory state in the central nervous system, those impulses which

---

Presented at the University of Minnesota by Dr. Harold G. Wolff as the J. B. Johnston Lecture on January 25, 1952. The contents of this communication will appear as Chapter XIV of the book, "Pain Sensations and Reactions" by James D. Hardy, Harold G. Wolff and Helen Goodell, now in press and published by Williams and Wilkins, Baltimore, Maryland. Appreciation is expressed to the latter for permission to print this manuscript in MINNESOTA MEDICINE.

From the New York Hospital and the Departments of Physiology, Medicine (Neurology), and Psychiatry, Cornell University Medical College, New York, N. Y.

enter the neuraxis result in an increase in intensity of pain sensation.

For those adjustments, feelings, and sensations from noxious stimulation to ensue, neural endings must be viable. It is not established, however, whether nerve endings *per se* have to be injured by the noxious stimulation, nor, indeed, that they need be stimulated directly. It may be that nerve endings are stimulated as a sequel of liberated products of injury, since, indeed, it has been shown that the latter can exert such an effect.

The Response

Although not all noxious stimulation and tissue damage give rise to pain sensation, they give rise to a host of other reactions essential to adjustment. Further, these reactions to noxious stimuli, although conditioned for the body's protection, may be so costly to the body economy as themselves to damage tissue, giving rise to further adjustments and secondarily to pain.

It is ironic that the protective and adaptive reactions to noxious stimulation may be so vigorous as to cause more damage and pain than the initial assault. Indeed, these phenomena of adjustment may become a greater threat to the integrity of the organism than the original damage. The fact that adaptive reactions *per se* may become a major threat to the organism is especially impressive when the individual reacts to the symbols of danger as he would to tissue damage.

Predictability is a feature of reactions to noxious stimuli when segmental levels are freed of the modifying influence of the suprasegmental apparatus, as in so-called "spinal" animals. But such unconditional reflexes are less predictable in the animal with intact nervous system. Patterns of reaction to noxious stimuli involving the highest integrative functions, dependent as they are upon many circumstances, influence lower or segmental reflexes, and reaction thresholds when measured in the intact individual are a feature of individual experience rather than being inborn.

Hence, "reaction thresholds" to noxious stimuli fall into two general categories: the one is relatively stable, fixed and highly predictable (i.e., the flexor reflex to noxious stimuli in a spinal cat); the other labile, dependent on many circumstances and only to a limited degree predictable (i.e., the conditioned reflex). When "reaction threshold" to noxious stimuli in the intact animal is defined in terms of skin resistance, blood pressure, "wincing," pulse rate, et cetera, it must be appreciated what a labile entity is being appraised.

The impulses arising from noxious stimulation have a strikingly varied summative effect as regards the number of nerve fibers involved in the noxious stimulation. However, these spatial summative effects are conspicuous only in the realm of simple and local reflex adjustments. There is no spatial summation as regards the intensity of pain sensation. Were this not so, intense pain would be omnipresent.

The pain threshold may be raised by a variety of alterations within and outside the nervous system, i.e., interference with function of the conduction pathways and central integrative apparatus, either reversible or irreversible; co-existence of other vivid sensations, particularly pain; distractions, suggestion, hynosis and the action of chemical agents known as analgesics and anesthetics.

Pains of high intensity resulting from noxious stimulation from the periphery is seldom more than of brief duration because such intense stimulation either (1) destroys the neural equipment implicated, or (2) so damages the tissue between the stimulus and the nerve endings as to prevent the stimuli from reaching nerve endings. On the other hand, mild pain may persist for months or years. Moderately severe pain may last for hours or days, but again is usually self-limiting because of local tissue alterations which reduce the number of neural impulses resulting from noxious stimulation.

Structures Involved

All neural impulses having to do with noxious stimulation and pain are funneled through the dorsal roots, the bulk ascending in the cord and brain stem through the ventral lateral tracts to the thalamus. There would appear to be no cortical representation of pain. Although the cerebral cortex is necessary to pain discrimination, it is doubtful whether any one part of the cerebrum is specifically involved.

It seems likely, however, that major brain damage, particularly in the frontal lobes, interferes with the capacity to discriminate among the intensities of pain sensation. Neural impulses from noxious stimulation may be conveyed by fibers of many sizes following various routes to the dorsal ganglia and up the cord. It is, however, likely that the fibers involved in aching and burning sensations are anatomically and physiologically different from those involved in pricking pain. The latter apparently are phylogenetically more recent, are myelinated, larger, and conduct impulses more rapidly.

Short intercallated neurones within the segments of the cord, brain stem and probably in the cerebral cortex are essential to the phenomenology of pain sensation since they are responsible for the maintenance of augmented central excitatory states such as produce itching, hyperalgesia, altered discrimination of intensity, emotional excitement and complicated behavior patterns.

Central Excitatory States

The damaging of tissue may set in motion hyperexcitatory states which require very little additional peripheral stimulation for their maintenance. Such hyperexcitatory states may become self-perpetuating, but once interrupted may not be reinitiated. Central excitatory states are furthered and hindered by a variety of factors in the internal and external environment and only in part are they dependent upon impulses from the area initially damaged. However, heightened excitation in the suprasegmental apparatus may be built up by prolonged mild noxious stimulation, either from the periphery or from lesions within the brain itself.

Also, central excitatory events at segmental or suprasegmental levels are of importance to an understanding of referred pain. "Referred" pain, or pain experienced at a site other than that of noxious stimulation is to be distinguished from pain which arises as a sequel of motor or vasomotor reflex effects. Such pain results from noxious stimuli frequently of intensity below the level necessary for the production of pain sensation. Both types of pain are, in a sense, subsidiary effects; referred pain, results from a spread within the neuraxis, producing sensations at a remote site; the second type of pain results from "spread" within a segment ending in reflex contraction and tissue damage. These effects are easily confused and are often spoken of interchangeably, but actually represent different processes having a common denominator in a heightened level of central excitation. Thus, although noxious stimulation of tissue must be of a given intensity to evoke pain sensation directly, nonetheless even those stimuli insufficiently intense to evoke pain may, by altering central excitatory states, become involved in pain sensation. However, far more frequently noxious stimulation of such low intensity induces local adjustments essential to homeostasis, without evoking the sensation of pain.

Most relevant to the intensity of central excitation and pain is so-called "rest"— a state variously defined by different cultures. Consequently there is no general unanimity of opinion concerning its operation. Perhaps basically, however, it is that state in which reparative or restorative forces are fostered and exceed destructive forces. Such a view circumvents the question whether mobilization vs. immobilization, or one type of inactivity vs. another or one body posture vs. others is operatively more effective. It defines merely the fact that under a given set of circumstances reparation prevails. At the simplest physiological level, this is accomplished by means that reduce noxious stimuli and local vasomotor and skeletal muscle effects which in themselves produce pain or maintain a state of central excitation of a costly and destructive nature. The diminishing of excitation within the neuraxis can be accomplished by the use of agents that have very little pain-threshold-raising effect (i.e., barbiturates administered intravenously may reduce strikingly the amount of pain experienced by those exhibiting secondary reflex skeletal muscle contraction). But relevant also in a consideration of effects of "rest" is the removal of individuals from stressful life situations created by personal and social pressures. Again by lowering the general level of excitation within the neuraxis, pain is reduced or eliminated. This may be attained by "invalidsm." Also, "complete bed rest" in a society that views the "sick bed" as sanctuary, may have such an effect, assuming that the individual's frustration of his own drives and goals is outweighed by the immunity and even prestige afforded by being "sick in bed." Further factors that reduce excitation within the nervous system are sleep, the elimination of prolonged or excessive effort, relative freedom from harassing conflicts and anxieties, and the delegation of responsibilities and guilt to the group at large and to other individuals. Moreover, the passage of time with its opportunities for alterations and adaptations may be a most important factor in the waning of central excitation.

The phenomena of itch and secondary hyperalgesia are closely linked, both representing local augmentation in the central excitatory state. Itch does, however, depend as well upon low frequency impulses from noxious stimulation of low intensity. Yet these impulses must occur sufficiently frequently to evoke a sensation with the peculiar features which give itch its name. Itching is augmented during periods of skin vasodilatation. During the actual itching, which is phasic and seldom of long duration in any one area, the pain threshold is lowered. With the introduction of additional noxious stimuli such as results from pin prick or "scratching," the itch sensation is promptly dispelled. Similarly, the application of cold reduces itching in contrast to heat which augments it. States of emotional tension, fatigue, frustration and depression augment itching. Mild analgesics reduce or eliminate itch sensation.

From such studies on secondary hyperalgesia and the allied sensation of itch, interest has focused upon the degree of central activity which may occur at a number of levels within the neuraxis. The intensity of excitation at the highest levels, stemming from the individual's adjustments to a variety of environmental and social circumstances, may be as significant as that at the segmental level to which impulses arrive from damaged tissue.

On the other hand, an understanding of the nature of secondary hyperalgesia and an appreciation of the fact that relatively few impulses from the periphery may maintain a "feedback" system exhibiting itself in part as pain, has once again focused interest on the expediency of blocking noxious impulses at their source. Interruption of noxious stimulation even temporarily may lower the level of central excitation and interrupt a cycle of events which has become almost self-sustaining. Hence, as indicated above, painful states in areas exhibiting either secondary hyperalgesia or painful reflex vasomotor and skeletal muscle effects from such heightening of excitation within the neuraxis, when interrupted, sometimes do not recur.

Procainization terminates the pain from contracted skeletal muscle either by blocking afferent impulses from the contracting tissue or by altering the contractile state of the muscle. Secondary hyperalgesia, either superficial or deep, may be dispelled by blocking afferent impulses through the use of local anesthetic agents, or by means of counter irritants.

A dramatic instance of the interplay of the effects of low intensity peripheral noxious stimulation and the effect of social and personal pressures in a maladjusted individual is witnessed in the intractable pain exhibited by some amputees. Such persons experience prolonged intractable pain, associated with kinesthetic experiences of the amputated part. Sometimes the elimination by local nerve block or by operative removal of a scar about the terminal portion of the severed nerve terminates this phenomenon. At other times, however, a self maintaining system of excitation has apparently become so well established that neither operative removal of scars, interruption of nerve pathways or even serious brain damage can complete eliminate it.

Factors that Modify Perception and Reaction to Pain

This consideration of the general level of excitement within the neuraxis, as indicated earlier, leads directly to a consideration of the individual's reactions to the the sensation of pain *per se.* Impulses reaching the neuraxis, regardless of whether they evoke pain, modify neural activity in such a way as to effect moods, feeling states and behavior patterns. Pain sensation can evoke responses beyond those appropriate, and out of all proportion to the danger of the situation. Inversely, pain sensation can be a factor in suppressing reactions because of an appreciation that no genuine threat is involved or that the assault can be readily withstood. In other words, the response to pain sensation depends to a greater or lesser degree on an individual's past experience and the meaning of pain sensation in terms of threat. The attitude of the society in which the individual finds himself and the latter's own point of view about pain sensation, although they do not modify the pain threshold and the ability to discriminate the intensity of pain sensation, become factors which augment the protective-adaptive patterns or repress them.

Remarkable tolerance for mild pain can be developed and maintained through such unrelated agencies as chemical substances, brain damage, group pressures and the reassurance of other individuals. Also, reactions of maximal strength can be elicited by stimulation at threshold intensity and in properly conditioned individuals by stimulation even of sub-pain threshold intensity. Inversely, placebo agents become remarkably effective in the relief of "suffering" even when pain is of moderate intensity.

All agents known as analgesics raise the pain threshold and alter perception of pain. However, the suppression of sensation is usually not as important an action as regards pain relief as are the effects upon reactions to noxious stimulation and to pain itself. Thus, the pain of a patient in labor is greatly reduced following administration of an opiate, without alteration in pain threshold or in ability to discriminate differences in pain intensity. Analgesics alter reaction patterns to pain by inducing relaxation, feelings of well-being, and sleep. The untoward aspect of these effects is that only those agents which have conspicuous and perhaps, from a social point of view, dangerous "side effects" best relieve suffering. Clearly exhibiting the "defects of their qualities," they present a dilemma, since the very effects which make for usefulness as analgesics, make for danger of addiction for those who suffer, regardless of whether the suffering is induced by noxious stimulation of bodily tissue or by threatening circumstances resulting from interpersonal or social stresses. The search for agents that raise the pain threshold alone continues, though, to date there is nothing to indicate that the possibility of finding one exists.

Appreciable differences concerning pain-threshold-raising properties are exhibited by such varying classes of agents as represented by morphine, codein, meperidine and the antipyretics. In general, the coal tar products in maximal amounts raise the threshold as so to eliminate 2 dol pain. Codein and meperidine in ceiling amounts raised the threshold so as to eliminate pains of 2 to 4 dols intensity. Morphine may eliminate pains of 4 to 6 dols intensity. But pains of 6 to 10 dols intensity cannot be eliminated without anesthesia, although they may be reduced to 3 to 4 dols intensity.

Whether the primary hyperalgesia be due to peripheral tissue damage or to damage in the conducting peripheral pathways, the pain threshold is lowered. Indeed, it may be so lowered that even those centrally acting analgesics capable of eliminating 4-6 dol pain are incapable of bringing the threshold up to the usual level. Effective procedures are those that prevent further stimulation of the damaged parts. After extensive skin burns, for example, the collection and drying of the surface serum usually gives the organism precisely this kind of protection. In those with peripheral neuropathy, relief from weight bearing, even that of the slightest covering, and the lessening, by exposure, of the heat produced by the individual's own body serve such a need.

The Significance of Pain in Human Adjustments

Man's ability to experience pain is not essential to a suitable biological adjustment. Children congenitally without the capacity to experience pain, at least when surrounded by pain-sensitive adults, adequately adjust themselves to their environment, as do persons who have had pain pathways surgically interrupted. Since, with exposure to noxious forces, the rate of tissue damage, rather than the amount or seriousness of such damage, determines intensity of pain, the latter is a poor indicator of the gravity of the subject's plight. Moreover, when injury is slowly- or non-progressive, even though extensive and ominous, little or no pain may be experienced. Persons critically ill, as with terminal neoplastic disease, and those gravely injured do not inevitably experience intense pain. Hence man has been obliged to develop other means of protecting himself and pain becomes of secondary importance to diagnosis. Alarm or defense reactions identical in pattern to reactions to intense pain may be initiated by any stimulus if that stimulus has been previously associated with injuries, dangerously threatening situations, or frustrations. As a matter of fact, the bulk of such reactions involved in common experience are initiated by non-painful stimuli.

In a variety of cultures, the recognition that a certain amount of pain is an inevitable consequence of living coupled with its appreciation that a pattern of complete avoidance of pain endangers the attainment of full maturity has been the basis for the development of the thesis that some pain is a "Good thing" (aspects of Christian doctrine, Stendahl, C. S. Lewis).

A feature of rapidly changing mores and one which is conspicuous in our culture is epitomized in the question, "How much should I put up with?" This plaint or query is especially conspicuous in cultures where the importance of the individual is stressed. This uncertainty arises from failure to distinguish between those aspects of man's relation to his universe that may change rapidly and those that must change slowly.

Certainly, pain sensation is a prime provocator of adjustment to environmental stimuli and, as such, is a highly important biologic function for man. It grossly defines the limits of man's life, but symbols and threats of pain soon become substitutes for noxious stimulation. Moreover, danger, threats to security, loss of love or disapproval by group or individual evoke the same protective and adaptive reactions and almost the same feeling states, emotions and behavior patterns as does noxious stimulation. This illuminates the nature of human protective reactions; and yet, on the other hand, the similarity of response has blurred the distinction between the sensation of pain and the reaction to noxious stimulation and pain.

ANALYSIS OF THE EFFECTS OF NOXIOUS STIMULATION

A. **Reactions not Dependent on Consciousness (Nociception)**

1. Effects at the Site of Tissue Damage
    - Inflammation, Cellular Death and Electrical Potential Changes
2. Integrated Reflex Effects
    - Pilomotor
    - Skeletal Muscle Contraction
    - Gastrointestinal
    - Sudomotor
    - Neuroendocrine
    - Humoral
3. Local Lowering of Threshold for Noxious Stimulation and Heightened Central Excitatory State

B. **Reactions Involving Consciousness: "The Pain Experience"**

I. Pain Sensation

1. Dimensions
    - (a) Localization: Site Extension Movement
    - (b) Quality Burning Pricking (Itching) Aching
    - (c) Intensity Threshold to 10½ Dols
    - (d) Temporal Aspects
        - Frequency Rhythmic Pulsatile Periodic
        - Duration Diurnal Seasonal
2. Modifying Factors
    - (a) Admixture of Other Sensations
        - Pressure Fullness Tightness Et cetera
        - Numbness Heat Cold
    - (b) Factors Increasing and Decreasing Intensity Primary Hyperalgesia
        - Secondary
    - (c) Factors Modifying Site Quality and Temporal Aspects

II. Feeling Mood Attitude Bodily and Behavior Reactions to Pain Sensation

1. Individual and Cultural Factors Conditioning Reactions to Pain Sensation
    - (a) Past Life Experience
2. Agents and Procedures Altering Reactions to Pain Sensation
    - (a) Analgesics and Other Pharmacodynamic Agents
    - (b) Suggestion Distraction and Hypnosis
    - (c) Life Setting of the Pain Sensation
1. Concurrent Adaptation Problems
    - (d) Reversible and Irreversible Alterations in Brain Function
        - (1) Sleep
        - (2) Brain Injury
        - (3) Et cetera.

The magnitude of protective responses induced by pain is based in large part on the way the affected subject perceives it. Perception depends upon a multiplicity of factors including the genetic equipment, basic individual needs and longings, earlier conditioning influences, the host of later life experiences and the nature of cultural pressures. The common denominator, as regards magnitude of reaction to pain, indeed is the interpretation of an event as more or less threatening.

This follows because the response may be in terms of a conditioned pain stimulus, which, though slight as regards its destructive effects on the organism, nevertheless has taken on, because of earlier experience, implications of grave danger. Hence, in man it is the response to pain *per se* that becomes of major importance, and indeed is capable of becoming a greater threat to survival than the assault.

Moreover, the response, regardless of the personal significance of the noxious stimulus, may be a function of the pre-existing level of central excitation. The latter, in turn, is a reflection of the cumulative effects of the various noxious stimuli of life stress, and in defining the magnitude of central excitation, shapes the magnitude of the response.

In brief, pain sensation has a basic significance in earlier life adjustments of man, though it becomes less and less essential with growing individual experience. Indeed, noxious stimulation and pain may evoke reactions that are more dangerous than the assault, and may even threaten survival. Those who would deal with pain as therapists must concern themselves especially with reactions to pain. The magnitude of protective reactions are dependent in part on concurrence of noxious stimuli, perhaps of low intensity, arising from parts remote from the main noxious source, as well as upon other non noxious, but disagreeable stimuli.

Moreover, in the total pain experience not only the immediate setting of the pain, but the meaning of such pain for the individual in terms of his past must be appreciated. Hence, man with the capacity to react defensively to symbols of danger is especially vulnerable, since he reacts not only to noxious stimuli but to a host of threats and indeed, may dangerously overreact to both, using both appropriate and inappropriate protective patterns. It thus becomes clearer why a physician who deals with the broader aspects of the sufferer's life experience and so makes efforts to support him in every way during a period of stress, is often more effective in a crisis than one who deals merely with the source of noxious stimulation. A transient painful incident for man is only one of a series of threatening circumstances to which he is exposed, his recent and remote past being perhaps the major factors in defining what the pain means to him and how he will meet it.

The Nature of the Pain Experience

It is appropriate to return again to the concepts which have been held of the nature of pain and to suggest a thesis which is compatible with present knowledge. Widely held in the nineteenth century, the intensive theory proposed to account for pain as the end result of strong stimulation of any sensory equipment, for example, visual, auditory, thermal or tactile. Such a view is not supported by data now available.

The ancient concept of pain as an emotion is supported by the newer information, at least to the extent that emotions and attitudes are among the identifiable reactions to pain. However, pain is a sensation, and, like other sensations, is mediated by specialized neural equipment. The adequate stimulus for pain sensation is any force resulting in the sufficiently rapid damaging of tissue, and, within limits, the rate of tissue alteration determines the intensity of pain.

Better to understand the phenomenology of pain, it was found desirable to separate the responses to noxious stimulation into (a) those not dependent upon consciousness, and (b) those involving consciousness. The former includes the automatic reflex responses; the latter includes on the one hand the pain sensation, and on the other hand the feeling, mood and attitude reactions largely determined by the past experience of the individual to the automatic responses and to the sensation of pain. It is the interplay of these fundamental components within the individual which comprises the pain experience. Such a broad specification was found necessary if the pain experience is to include the reportable feeling states and other sensations correlated with the report of pain. The reactions to noxious stimulation not dependent upon consciousness and those represented by the pain experience have been shown to be intimately interwoven.

Clean your fingers before you point at my spots.—Benjamin Franklin

The prudent will prepare themselves to encounter what they cannot prevent.—James Russell Lowell

OSTEITIS CONDENSANS ILII

The Relationship to Juvenile Epiphysitis

WALTER H. UDE, M.D.
Minneapolis, Minnesota

IN A PREVIOUS publication,[6] the author advanced the theory that osteitis condensans ilii is a direct result of juvenile epiphysitis of the sacro-iliac joints. This theory was supported by the report of six cases in which the condition was associated with residual changes of juvenile epiphysitis of the dorsal spine (Scheuermann's disease). Since this publication I have seen more than thirty additional cases of condensing osteitis ilii with co-existing Scheuermann's disease. My original observation, therefore, has been confirmed. The similarity of the degenerative changes in the spine and in the sacro-iliac joints, together with the constant co-existence of the spinal and the sacro-iliac condition, has now convinced me that these two are intimately related and result from the same original disease, juvenile epiphysitis. That the sacro-iliac joints are much less commonly involved than the spine is probably of little significance. The significant fact is that when they are definitely found to be involved, the changes in and adjacent to the joints are of the same character as seen in Scheuermann's disease.

Until the publication of my preliminary report, no definite etiological factor had ever been successfully assigned to condensing osteitis ilii. Most recently Folke Knutson,[4] in his presentation before the Sixth International Congress of Radiology in London in 1950, was not aware of any known causative entity. Radiologists commonly added the words "etiology unknown" to their interpretation of these cases. Most observers have considered it on a par with anomalies, with no recognizable relationship to symptoms. This position is not supported by the work of Hare and Haggert,[3] who reviewed the subject in 1945 and reported twenty-three patients observed in their clinic. Their youngest patient was twenty-three years of age. They quote Rendich and Shapiro, who were able to secure a biopsy during the performance of surgical fusion of the joint. This revealed a non-inflammatory calcium condensation in the osseous tissue. Hare and Haggert were not able to clarify the etiology of the condition. All of their patients came for examination because of low back pain, localized either to the lumbar or sacro-iliac region. In some instances the pain radiated downward into the lower extremities, occasionally simulating herniated disk. Shipp and Haggert[5] reviewed the same material and extended their observations to include 100 cases. All their patients were adult females, the oldest forty-four and the youngest nineteen years of age. They concluded that the condition occurs as the result of mechanical strain affecting an amphiarthrodial joint. They found the process to be reversible.

The roentgenologic features of vertebral epiphysitis have been described by deLorimier[2] and others. The demonstrable abnormalities seen immediately subsequent to the termination of the active stage of the disease consist mainly of structural changes in the shapes of the vertebral bodies, with a tendency toward wedge-shaped deformities, intra-osseous herniations of nuclei pulposi, or so-called Schmorl's nodes, and irregular cortical sclerosing changes around the margins of the vertebral bodies and of the margins of the Schmorl's nodes. These changes produce variations in the curvatures of the spine, mainly kyphosis, but also scoliosis, which is distinctly localized to the region involved. Slight narrowing of the intervertebral disks may be present, probably as an associated result of the Schmorl's nodes. In subsequent years, degenerative changes develop in the involved areas of the spine, which consist mainly of hypertrophic marginal lipping. This begins to be in evidence in the third decade of life, considerably earlier than in the average normal. In my observations there is also an increasing degenerative change in the intervertebral disks as shown by further narrowing of the disks. In my previous report the youngest patient, aged twenty-six, showed definite hypertrophic lipping although she presented relatively minimal structural changes of the vertebral bodies. Since that time I have observed a younger patient, an unmarried girl, aged eighteen, showing condensing osteitis of the left sacro-iliac joint, with Scheuer-

---

Dr. Ude is Associate Clinical Professor, University of Minnesota.

mann's disease of the dorsal spine, without any degenerative changes. I believe this is the youngest case ever reported. In my previously reported Case 6, and in several additional cases seen more recently, I also observed condensing osteitis extending from the vertebral plates into the adjacent cancellous structure of the vertebral bodies, very similar to the condensing osteitis in the ilia. It is assumed that all of these degenerative changes superimposed on the structural changes are due to faulty statics or mechanical strain, and are on the same basis as the degenerative findings seen in the hip joints subsequent to juvenile epiphysitis.

The known facts about condensing osteitis ilii might be itemized as follows:

1. The condensing osteitis is a homogenous sclerosing process or calcium condensation in the ilium directly adjacent to the sacro-iliac joint. It may be unilateral, but more commonly is bilateral. In a minimal degree of involvement it may be limited to the lower portion of the auricular process of one ilium. My youngest patient, aged eighteen, is of this type. In the more marked cases the calcium condensation extends along the entire vertical diameter of the auricular processes of both ilia, and flares laterally into the adjacent bony structure.

2. The sclerosis is usually limited to the iliac side of the joint, but occasionally the sacral side is involved. Folke Knutson reported five cases out of thirty-seven with sacral involvement, and I have found it in two of my recent cases.

3. Hitherto, the joint was thought to be uninvolved. Case 1 of my previous report showed evidences of degenerative arthrosis in the involved sacro-iliac joint of a unilateral condensing osteitis, the uninvolved joint being apparently normal. Folke Knutson also found this complication, thus confirming my observation. Since then I have seen several other patients with distinct degenerative changes in the involved joints.

4. Biopsy has revealed the condition to be a non-inflammatory calcium condensation in the osseous tissue.

5. The condition is found predominantly in women, but a small proportion, about 5 per cent, has been found in men.

6. The age distribution in my series is from eighteen to sixty-six, but the condition is usually discovered between the ages of twenty and forty. Hare and Haggart gave their lowest age incidence as twenty-three, but in the extension of this study Shipp and Haggart reported a patient nineteen years of age. These authors also present evidence that the sclerosing process seems to be reversible, which may account for the rare incidence of the condition in older individuals.

7. The predominant symptom is low back pain. This may be lumbar or sacro-iliac in location, and may radiate into the lower extremities.

8. The condition is not infrequently associated with a degenerative process in the symphysis pubis, with sclerosing changes in the adjacent portions of the pubic bones, very similar to the changes in the ilia.

The unknown facts about osteitis condensans ilii are mainly as follows:

1. The cause of the condition has been unknown.

2. The fact that it occurs predominantly in women has not been satisfactorily explained. Hare and Haggart, and Shipp and Haggart point out that in the gynecoid pelvis the sacrum tends to be of the horizontal type, while that of the android pelvis is more oblique in position. It is possible that this may account for a variation in the distribution of the condensing osteitis. In the female, and in the male pelvis with a gynecoid tendency, the sclerosis may follow the typical pattern, while in the male with a distinctly android pelvis the sclerosis may be diffusely distributed over the entire auricular process and thus escape detection in the casual examination. I have observed a case of this type, a boy aged thirteen, who showed a marked Scheuermann's disease of the dorsal and lumbar spine. In addition he showed a fragmented calcification of the epiphyses over the crests of the ilia, and areas of decalcification of the margins of both sacro-iliac joints. Subsequent observation revealed finally at the age of twenty-two an irregular serrated contour of the iliac crests, a distinct increase in calcium density to a depth of 5 to 8 millimeters of the articular margins of the sacrum and ilia at both sacro-iliac joints, and suggestion of reduction in width of the joint spaces as compared with the usual normal at this age. In another recent case, a man aged forty-two, the findings were as follows:

> "There are old structural deformities in the lower dorsal and upper lumbar vertebral bodies, with multiple Schmorl's nodes, with moderate hypertrophic marginal lipping, especially in the lower dorsal region, and with some degenerative changes in the intervertebral disks in the lower dorsal and upper lumbar area. The findings are characteristic of the residual changes from old juvenile epiphysitis with secondary degenerative arthrosis. There is questionably a slight narrowing of the lumbosacral disk, but the lower lumbar disks are otherwise within normal limits in width, with the Schmorl's nodes involving also the lower lumbar segments. There is a localized condensing osteitis in the upper portions of the sacro-iliac joints, mainly in the adjacent portions of the ilia, and resembling the changes produced by osteitis condensans ilii. It is, therefore, probable that this represents a variation of condensing osteitis ilii, namely the type of process more commonly occurring in the male pelvis because of the sex variation in the developmental structure of the pelvis."

If subsequent observations on large groups of cases of Scheuermann's disease should show this type of change in the sacro-iliac joints in a sufficiently large group of males to compare favorably with the combined incidence of Scheuermann's disease and condensing osteitis in the female, one would be on fairly firm ground in accepting this as the more common manifestation of this condition in the male. Into this picture one would then have to adapt the presence of a gynecoid tendency in the male patient with typical condensing osteitis.

It must be conceded that factors associated with pregnancy may be responsible for the more common development of the sclerosing osteitis in the female. The damage to the joints by the epiphysitis may not have been sufficient to produce the sclerosis, but the physiological changes in the joints as a result of pregnancy, coupled with the increased weight bearing strain, may be the immediate causative factor in the appearance of the sclerosis. To establish this one should show the absence of the sclerosis before the onset of the pregnancy. This assumption would also explain later reversal of the process. The basic causative factor, however, is the pre-existing arthrosis from juvenile epiphysitis.

3. The most important question to the patient and the attending physician is whether the condition is of symptomatic significance, and what is its treatment. If we assume that the condition arises on the basis of alteration of the articular surfaces by juvenile epiphysitis, and that a majority if not all such joints undergo a degenerative change, then it may also be assumed that such a degenerative arthrosis gives rise to low back pain. In turn, this concept would govern therapeutic procedures.

4. Can one suspect the presence of osteitis condensans ilii when Scheuermann's disease is demonstrated in the spine? Usually we have found the sacro-iliac changes first, and later substantiated the presence of spine changes. Very recently a case presented itself in which this procedure was reversed. The patient, a married woman, aged thirty-nine, gave a history of injury to the shoulder and dorsal spine region. Films of the dorsal spine revealed marked changes resulting from juvenile epiphysitis, including the sclerosing changes above referred to in Case 6 of the previous report, with the sclerosis radiating into the cancellous structures of several vertebral bodies. Later, re-examination to include the sacro-iliac joints revealed a typical condensing osteitis in one of the joints. The inclusion of a film of the sacro-iliac region in all cases of vertebral epiphysitis, either active or old, may therefore yield valuable additional information.

Consideration of the problem of sex incidence of vertebral epiphysitis should not yield any additional confusion. It is a very common condition, and in a general group of patients is found about equally common in both sexes. Brailsford[1] states that it is more frequently found in female patients, while deLorimier found it more common in males. It is possible that these observations were made on material with unequal sex distribution, and that one may therefore assume that sex is not a determining factor in the incidence of this disease.

Conclusions

1. Osteitis condensans ilii has been shown to be co-existent with vertebral epiphysitis in all cases which have recently come under my observation.
2. Osteitis condensans ilii has been shown to be associated with changes in the sacro-iliac joints suggestive of degenerative arthrosis.
3. The changes in the sacro-iliac joints have been shown to be of similar nature to those in the spine in vertebral epiphysitis.
4. The demonstration of osteitis condensans ilii in unmarried women, in a young unmarried woman aged eighteen, and in male patients, casts distinct doubt on the premise that pregnancy is the etiological factor, although it does not eliminate it as a contributing factor in the actual de-

CORRELATION OF BLOOD SUGAR VALUES WITH GLYCOSURIA IN DIABETICS

ROBERT STEWART FRASER, M.D.
Edmonton, Alberta, Canada

BLOOD SUGAR levels and urinary glucose excretion are two important laboratory aids used in establishing control in diabetics. Much has been written in the vast literature of diabetes on the merit of these estimations. Joslin[5] states that "while the twenty-four-hour quantity of sugar in the urine is not an absolute measure of the degree of control of diabetes, still in the vast majority of cases it is an accurate index." He agrees with John[3,4] that the glucose excreted should not exceed 10 gm. daily. In this report, the criteria for control as judged by blood sugar levels were somewhat less rigid than those set by Joslin,[5] Duncan,[1] and John.[3,4] For purposes of this paper, a diabetic was termed "controlled" if the 7 a.m. fasting blood sugar was less than 130 mg. per cent and the preprandial values did not exceed 170 mg. per cent. Joslin believes that blood sugar levels in a diabetic should be normal before and after meals. Duncan does not consider that a patient is controlled unless the blood sugar values at 11 a.m., 4 p.m. and 10 p.m. are less than 150 mg. per cent, and the fasting morning value is between 70 and 100 mg. per cent. John requires a "normal or near normal" blood sugar before each meal and a morning fasting value of 100 mg. per cent or less.

The purpose of this study was to determine how many of those patients who excreted 10 or less gm. of glucose a day in the urine could be considered controlled when judged by the blood sugar requirements described above. It also afforded an opportunity for assessing the value of the qualitative Benedict test as usually carried out for urinary glucose. It was not our intention to enter into the controversy concerning the merit of "chemical" control of diabetes, but only to present certain observations on the relationship of glycosuria to glycemia in patients with diabetes.

Method

The patients investigated comprised a group of diabetics who were admitted to hospital for various reasons and who were under the care of their private physicians. Two twenty-four hour studies were made on eleven of twenty-two patients. The first was made soon after admission, before any changes had been made in diet or insulin dosage. The second study was made just prior to discharge. Only one twenty-four-hour study was made on the remaining eleven patients, either because there had been no change in treatment or because the patient left the hospital before further investigation could be carried out. One patient who did not have diabetes was added to the group for purposes of comparison.

Procedure

1. Blood sugar estimations were made at 7 a.m., 11 a.m., 4 p.m., 10 p.m. and 7 a.m. the following morning (Folin-Wu-method).
2. All urine excreted was collected in four periods corresponding to the blood sugar estimations.
3. Urine specimens were collected, after the bladder had been emptied, at times which coincided as closely as possible to the times of the various blood withdrawals. These are reported in the usual way to show from 0 to ++++ tests for urinary sugar (Benedict qualitative reagent).

Results

It can be seen in Tables I and II that in eleven examinations a urinary excretion of less than 10 gm. of glucose in twenty-four hours suggested that diabetic control had been attained. In each case, however, the corresponding fasting or preprandial blood sugars or both did not fall within the prescribed limits. In one-third of thirty-three examinations the twenty-four-hour urinary glucose excretion did not correctly mirror the state of diabetic control when this was assessed by blood glucose levels. Nevertheless, if both a normal fasting blood sugar and a urinary glucose excre-

---

Dr. Fraser's present address: Department of Medicine, University of Minnesota Hospitals, Minneapolis, Minnesota.

tion of 10 gm. or less in twenty-four hours were required of these patients, the state of control in all of them could be correctly determined.

* Controlled when judged by urinary glucose excretion but not controlled when assessed by blood glucose levels.

It was reasonable to expect that these patients would show elevated renal thresholds for glucose. Renal thresholds should ideally be determined by reference to the arterial glucose content, but it has been shown that in diabetics there is little difference in arterial and venous glucose levels when blood is taken in the post-absorptive state.[6] In four of ten patients negative qualitative Benedict tests were noted at times when the blood glucose values exceeded 200 mg. per cent. In other instances, the urine showed only a trace of sugar with similarly high blood sugars. Marble[7] has summarized the opinions of a number of workers concerning the presence of high renal thresholds in diabetic patients. Although some believe that the renal threshold tends to rise as the disease progresses, especially if nephritis or hypertension develops, others have found the higher thresholds in young patients and those with diabetes of recent onset. Two of the four patients cited had hypertension, and although the blood pressure was normal in the other two, both had a history of diabetes of longer than ten years. (Pts. 10, 14, 15, 19.)

The quantitative Benedict urinalyses carried out at the same time as the blood sugar estimations were unreliable indices of diabetic control. In Patient 3 (series a), a one plus result was found when the blood sugar was 72 mg. per cent, yet six days later (series b) a negative test was associated with a blood sugar of 172 mg. per cent. Patient 19 showed three negative urine sugar tests at times when the blood sugar had not fallen below 210 mg. per cent. Several other examples follow, with the urine Benedict tests in parentheses. Patient 10, 230 mg. per cent (++), 280 mg. per cent (+); Patient 12, 325 mg. per cent (Trace), 260 mg. per cent (++++; Patient 15, 320 mg. per cent (++), 250 mg. per cent (++++).

Mollerstrom,[8] Forsgren[2] and others believe that there is an endogenous periodicity of carbohydrate metabolism. An examination of the twenty-four-hour blood sugar curves reported by Sprague and Newson[9] revealed that six out of eight of their diabetic patients, who were receiving no insulin, developed their highest blood sugar level at 11 a.m. At the time of admission to hospital ten of the patients reported in this study were receiving no insulin. In seven of these patients (Nos. 1, 7, 9, 10, 16, 19, 21) the highest blood sugar level was reached at 11 a.m. In two patients (Nos. 6 and 13) it occurred at 10 p.m. and in one patient (No. 2) at 7 a.m.

Summary

Blood sugar levels were determined on twenty-two diabetic patients and one normal person at 7 a.m., 11 a.m., 4 p.m., and 7 a.m.

A twenty-four-hour urinary glucose excretion was determined in each case.

A qualitative Benedict test for urinary glucose was made each time a blood sugar sample was obtained.

Consideration of the twenty-four-hour urinary glucose excretion alone led to an erroneous conclusion about the state of diabetic control in one-third of the cases.

If both the fasting blood sugar and the twenty-four-hour urinary glucose excretion were used in this assessment the state of diabetic control could be correctly determined in all patients.

The qualitative Benedict test was found to be an unreliable guide in determining the state of diabetic control.

The highest blood sugar value in patients not receiving insulin was most commonly found at 11 a.m.

Acknowledgment

The author wishes to acknowledge the kind co-operation of all the physicians whose patients were subjects in this study and the kind advice of Dr. P. H. Sprague, who suggested this study. He would also like to express his appreciation to the laboratory staffs of the University of Alberta and Royal Alexandra Hospitals for technical assistance.

OSTEITIS CONDENSANS ILII

(Continued from Page 543)

velopment or exacerbation of the sclerosis or of the symptoms in female patients. The theory is advanced that the apparent high incidence of this condition in female patients is due to the difference in weight-bearing impact resulting from the more horizontal position of the female sacrum, thus giving rise to the typical sclerosing changes, while in the android pelvis the changes are distributed more diffusely over the more obliquely placed articulation, and are therefore less easily recognized.

5. Juvenile epiphysitis of the sacro-iliac joints is considered to be the etiological factor in condensing osteitis ilii.

BLADDER REGENERATION

Case Report and Review of the Literature

EDWARD J. RICHARDSON, M.D.
Saint Paul, Minnesota

THE PHRASE "bladder regeneration" is unusual and may be confusing.

Regeneration means the replacement of a lost part in such a manner that the newly formed part corresponds with the lost one in form, structure and size. This is not to be confused with compensatory hypertrophy.

The more developed the animal species, the less is the power to regenerate. In man the power of regeneration is confined to regeneration of tissues *per se.*

A review of the literature reveals that in 1887 Busachi[1] reported regenerative processes in smooth muscle fibres after the seventh day following injury to the prostate, intestine, and uterus.

In 1888, Tizzoni and Poggi (quoted by Ravasini[5]) resected the bladder in a dog and substituted for this a segment of small bowel. Normal bladder function was restored, but when the animal was sacrificed after several years and examined at postmortem it was found that a new bladder had been formed and the segment of bowel had become a useless diverticulum. Ravasini also cited an animal experiment of Schwartz who observed bladder regeneration in a dog. He had removed the entire bladder except the neck, trigone, and ureteral orifices. Ravasini himself reported a clinical case of carcinoma of the bladder in which he removed the entire bladder except the left half of the trigone and a small portion of the adjoining wall. A cystogram made 8 weeks postoperatively showed a newly formed normal appearing bladder.

In 1923 Schiller[6] studied bladder regeneration in rabbits after resection of the bladder down to the trigone. One animal was operated on twice and formed a new bladder after each excision. He operated on nine animals. Two died. The other seven all formed new bladders. All the animals were later sacrificed and histologic studies showed in all cases slender individual muscle cells, fibres, and bundles. This confirmed his opinion that the process was one of regeneration rather than hypertrophy and hyperplasia.

Kretschmer's[3] work in 1927 on rabbits supported Schiller's findings. At about this same date, Perlman[4] also demonstrated bladder regeneration in dogs.

Folsom, O'Brien, and Caldwell[2] in 1940 reported eight cases of subtotal cystectomy in the treatment of Hunner ulcer as well as experimental work on bladder regeneration in dogs. In the eight cases of Hunner ulcer there was one failure. This was thought due to pre-existing upper urinary tract infection. The authors believed that this operation was contraindicated in patients with serious upper urinary tract infection. The other seven patients had no urinary tract infections prior to operation and all had good results as shown by normal postoperative cystograms and relief of symptoms. The ages of the patients, all women, were thirty to sixty-five years. Symptoms had been present from four to twenty-seven years. Follow up examinations were made in one case seventeen years, in one case over eight years, and in the remainder from two years to a few months following operation. The cystograms in two cases showed bilateral ureteral reflux which caused no symptoms and which could not be explained.

In this excellent paper the authors also reported their results with subtotal cystectomy on eight adult female dogs. There were two deaths: one from peritonitis a week after operation and the other from distemper after three months. The other animals were sacrificed, and postmortem examinations showed complete re-establishment of bladder size in all cases. Histologic studies showed the process to be regeneration and not hypertrophy and hyperplasia.

From these studies it is evident that the human bladder as well as the bladder of dogs and rabbits has the power to regenerate. Additional proof of bladder regeneration will be evident from the following case report.

Case Report

Mr. E. P., aged sixty-six, was first seen on August 2, 1950, complaining of blood at the beginning of urination. Transurethral resection had been made elsewhere in 1935 and again in 1949 because of vesical neck obstruction. Both surgical procedures gave relief from the obstructive symptoms.

The patient stated that he voided with a good stream

and had good control. There was no history of pain, colic, or bladder irritation. He voided four to five times a day and had no nocturia. His only complaint was occasional hematuria at the beginning of urination for the past two to three months. He stated that he had been cystoscoped elsewhere about six weeks previously with negative findings.

The family history and past history were essentially negative.

Physical examination revealed a well-developed, well-nourished sixty-six-year-old white man in no distress. Pulse was 80. Blood pressure was 130/80. Heart and lungs were normal. Abdominal examination was negative. On rectal examination some little remaining prostatic tissue was palpable, which was moderately indurated but not suspicious of carcinoma. There was no residual urine. The other details of the physical examination were within normal limits.

Laboratory Studies.—Blood: hemoglobin 14.5 grams (87 per cent), white blood cells 6,350. Urine: specific gravity 1.019, pH 6, albumin negative, sugar negative, microscopic centrifuged results—10 to 15 white blood cells and 20 to 30 red blood cells per high power field. Blood urea nitrogen 12 milligrams per cent. Acid phosphatase 1.5 units.

On August 3, 1950, a cysto-urethroscopic examination was carried out under spinal anesthesia. The bladder and prostatic urethra were normal, and nothing was found to account for the patient's complaint of initial hematuria. As the instrument entered the bladder, it was felt to come into contact with the posterior bladder wall—which is not unusual. Further examination found a small rent in the mucosa of the posterior bladder wall which appeared to be not important. The instrument was removed, a Foley bag catheter was inserted, and the patient was returned to his room.

Catheter drainage was continued and antibiotics were given. Within twenty-four hours there was complaint of fairly severe lower abdominal pain. The temperature rose to 100°. Generalized abdominal distention developed, which was controlled by nasal suction and intravenous fluids. X-ray examination of the abdomen showed a paralytic type of ileus.

The diagnosis was now obvious: peri-vesical extravasation of irrigating fluid (distilled water) incident to injury of the bladder wall by the entering cystoscope.

The nasal tube was removed in a few days. The daily temperature elevation was between 100° and 101°, reaching a high of 101.8° on the seventh day, after which it returned to normal and remained so for the rest of the hospital stay. The white blood count varied between 6,000 and 11,700. The blood urea nitrogen was never over 20 milligrams per cent. By the third postoperative day, a mass about the size of a large lemon could be palpated abdominally above the pubic arch extending over to the right side. In spite of adequate catheter drainage this mass did not appreciably decrease in size.

On the seventh postoperative day the first cystogram was made.

Figure 1 represents a cystogram made one week after bladder injury and shows the marked degree of extravasation.

Figures 2 and 3 represents cystograms made respectively two and three weeks after bladder injury. Extravasation is still present.

The day following the last cystogram a cysto-urethroscopic examination was made under spinal anesthesia. Fairly normal appearing mucosa over the vesical neck and trigone was seen. Beyond this the only semblance of bladder wall and mucosa was a narrow strip of intact mucosa, extending for a few centimeters upward from the vesical neck in position of the anterior wall. Beyond this the surfaces visualized were in the form of necrotic crevices and pockets. It was evident that most of the bladder wall had sloughed out.

After removal of the cysto-urethroscope, bimanual recto-abdominal examination was made, which disclosed a mass of infiltration in relation to the bladder floor continuous with the right pelvic wall and right side of the hollow of the sacrum.

Surgical exploration of the bladder was made forthwith. This confirmed the findings of the cysto-urethroscopic examination: almost complete bladder slough. All of the bladder that was intact was the vesical neck and trigone and a small strip of mucosa anteriorly. Specimens of tissue taken from various areas of the perivesical spaces and wound cavity showed only abscess wall—no bladder muscle. An F22 Robinson catheter was introduced through the urethra and was drawn down into the vesical neck—in which position it was affixed to the glans penis with a suture of braided silk. The silk cord attached to its upper end was brought out through the wound. An F24 Robinson catheter was put in place with its end close to the vesical neck, brought out as a suprapubic tube, and fixed to the skin with a suture of braided silk. Drains were placed in the prevesical space.

The patient's postoperative course was uneventful.

Figures 4 and 5 represent cystograms made respectively two and three weeks postoperatively.

The patient was discharged from the hospital on the twenty-second postoperative day after a forty-four-day hospital stay.

At the time of discharge, the patient was leaking a small amount of urine through the suprapubic wound but was voiding frequently with fairly good control.

Examination three weeks later found the suprapubic incision completely healed. There was normal urinary control with a bladder capacity of approximately 150 cc. By the ninth postoperative week, the pyuria had cleared and the bladder capacity was 200 cc.

The last examination was on July 26, 1951—almost one year after operation. The patient was well and had no complaints. Urination was normal and the urine was negative. Bladder capacity was 350 cc.

Figure 6 is a cystogram made approximately one year postoperatively.

So here we have a patient whose entire bladder except for the trigone and vesical neck had completely sloughed as the result of extravasation secondary to instrumentation and then regenerated completely so that one year later he had a completely normally functioning organ—added proof of the ability of the human bladder to regenerate.

This not too well known phenomenon of bladder regeneration offers many interesting possibilities for future bladder surgery. There is still much work to be done along this line, and time alone will bear proof of its final results.

RECORD NUMBER OF LIVE BIRTHS

Live births for 1951 may have topped the all-time high set in 1947, but U. S. Public Health Service is waiting for final returns before making formal announcement. The 1947 figure for live births was 3,818,000 and the 1951 unofficial total is 3,833,000 but PHS points out this is just an estimate and the totals are too close together to make any claims for 1951's birth rate without final figures. One of the factors contributing to the rise was the continuing decline in infant mortality. For the fifteenth straight year the infant death rate declined, reaching 28.8 per thousand live births last year.

MATERNAL AND INFANT MORTALITY IN A RURAL HOSPITAL

DOUGLAS L. JOHNSON, M.D.

Little Falls, Minnesota

BECAUSE of an apparently high birth rate of premature infants in St. Gabriel's Hospital, it was felt a study of the entire maternal and infant mortality problem in this 100-bed rural general hospital was indicated.

Review of the maternal deaths during the ten-year period of 1942 through 1951 is indeed encouraging. During this period, there were 6,068 live births, and only one maternal death. In this case, death was due to acute yellow atrophy of the liver, and occurred in 1943. These figures produce a maternal death rate over the ten-year period of .16 per 1,000 live births. The rate for the state of Minnesota for the year 1950 was .58 per 1,000 live births.

To maintain this record, adequate prenatal care, careful and proper conduct of labor, and use of antibiotics, blood and blood substitutes when indicated together with proper postpartem care are vitally necessary.

The second phase of this study consists of a review of the stillbirths and neonatal deaths during the two-year period of 1950 and 1951.

From Table I, it is seen that the stillbirth rate for the two years was 17.3 and 17 per 1,000 live births. These are higher than the rate for Minnesota for 1950 of 16.3.

From the same table it is observed that the total premature rate was 41.1 and 69.9 respectively. For the state as a whole, the rate was 58 per 1,000 live births.

It will be noted from the table that there were eight full-term and five premature stillbirths in 1950 and seven full-term and six premature stillbirths in 1951. Table II presents these cases individually.

A brief summary of the probable causes of death in the fifteen full-term stillbirths permits grouping them as follows:

1. Cases 1, 4, 11, and 13—prolapsed cords.
2. Cases 3, 5, 7, 10 and 15—diabetes mellitus, toxemia, or other disease causing intra-uterine death with a macerated fetus.
3. Cases 2 and 8—pelvic and fetal disproportion.

TABLE I. REVIEW OF STILLBIRTHS AND NEONATAL DEATHS

	1950	1951
Total deliveries	763	803
Fullterm births	732	748
Fullterm stillborn	8	7
Premature births	31	55
Premature stillborn	5	6
Premature live births	26	49
Total live births	750	790
Fullterm stillbirth rate	10.6/M live births	8.8/M live births
Premature stillbirth rate	6.6	7.6
Total stillbirth rate	17.3	17
Total premature rate	41.1	69.5

4. Cases 9, 12, and 14—ruptured uterus or ablatio placentae.
5. Case 6—aspirated amniotic fluid.

It should be noted that there was only one autopsy in this group.

The causes of fetal death could be attributed to pre-eclampsia in Cases 2, 6, and 8; to maternal bleeding in Cases 5 and 11; to erythroblastosis in Case 1 and to fetal malformation in Case 7. In Cases 3, 4, and 10 there was no apparent reason for fetal death. There were no autopsies in this group.

It will be noted in the group of full-term neonatal deaths that three were due to multiple congenital malformations; four to aspiration of amniotic fluid or atelectasis; two to erythroblastosis; and one to pneumonia. Three of these infants were delivered by cesarian section. The high autopsy rate in this group of cases is particularly noteworthy.

A quick survey of this table shows that only one of these premature deaths was attributed to malformations, one to erythroblastosis, one to diabetes mellitus, and two to anoxia (premature separation and one prolapsed cord). The remaining twelve of the seventeen premature neonatal deaths can merely be listed as due to prematurity. It will also be noted that there were only two autopsies in this group.

Table VI is presented to show the various problems to be considered in an attempt to lower the neonatal death rate. Although this series is too small to have much significance attached to the percentage of each cause, a comparison is

---

Presented at staff meeting of St. Gabriel's Hospital, Little Falls, Minnesota.

TABLE II. FULL-TERM STILLBIRTHS
1950-1951

Case	Grav	Para	Weight	Pertinent Facts	Cause of Stillbirth
1	iv	iii	9 lb. 7 oz.	Forceps delivery	Prolapsed cord
2	iii	ii	11 lb. 11 oz.	Second stage one hour; mid forceps applied after version	Large infant, shoulder presentation
3	ii	i	5 lb. 12 oz.	Macerated fetus	
4	i	o	7 lb. 14 oz.	Large myoma extending 6 cm. below the external os	Prolapsed cord
5	i	o	6 lb. 3 oz.	Hypertension and albuminurea	Macerated fetus
6	ii	i	6 lb. 3 oz.	Normal pregnancy and delivery; half hour second stage; autopsy	Aspiration of amniotic fluid with hemorrhage in peritoneal, pericardial and pleural cavities
7	i	o	8 lb. 3 oz.	One premature previously died; no prenatal care	Diabetes mellitus; macerated fetus
8	ii	i	8 lb. 2 oz.	Previous delivery high forceps; baby OK; delivery breech; turned in office on two occasions. High forceps attempted Delivery by podalic version and breech extraction	Pelvic disproportion and prolapsed cord
9	iv	iii	7 lb. 6 oz.	Porosection	Ablatio placenta; uterine apoplexy
10	ii	o	9 lb. 7 oz.	Previous stillbirth	Diabetes mellitus; macerated fetus
11	ii	i	6 lb. 4 oz.		Prolapsed cord
12	iv	ii	6 lb.	Placenta previa and previous cesarian section Porosection	Ruptured uterus at 8 mos. gestation
13	iv	iii	7 lb. 4 oz.	Delivery by version, breech extraction	Shoulder presentation, prolapsed cord
14	xi	viii	7 lb. 1 oz.	Two previous abortions; cesarian section	Ablatio placenta
15	xii	x	6 lb.	All previous pregnancies normal	Macerated fetus

TABLE III. PREMATURE STILLBIRTHS
1950-1951

Case	Grav.	Para	Weight	Gestation Weeks	Pertinent Facts	Cause of Stillbirth
1	iii	i	4 lb. 12 oz.	31	Previous erythroblastotic baby recovered Increase in Rh antibody titre Delivered macerated fetus	Erythroblastosis
2	iii	o	4 lb. 3 oz.	31	Two previous stillborn and several miscarriages	Pre-eclampsia
3	iv	i	5 lb. 3 oz.	35	Two abortions caused by retroversion Breech presentation	Cause undetermined
4	v	iii	4 lb. 4 oz.	40	First delivery stillborn Macerated fetus	Cause undetermined
5	iv	o	2 lb. 10 oz.	26	Previous abortions	Bleeding entire pregnancy
6	i	o	1 lb. 9 oz.	33	Pre-eclampsia Macerated fetus	Pre-eclampsia
7	i	o	4 lb. 8 oz.	35	Macerated fetus	Hydrocephalus
8	i	o	4 lb. 1 oz.	37	Twins (one alive)	Pre-eclampsia
9	vii	v	2 lb. 13 oz.	28	One abortion	Macerated fetus
10	ii	o	2 lb. 11 oz.	26	One previous miscarriage (deformed fetus)	Macerated fetus
11	i	o	5 lb. 2 oz.	40		Ablatio placenta

TABLE IV. FULL-TERM NEONATAL DEATHS
1950-1951

Case	Grav	Para	Weight	Age at Death	Pertinent Facts	Cause of Death	Autopsy
1	i	o	7 lb.	¾ hr.	Cesarian section—Gen. anesthesia	Aspiration pneumonitis	Yes
2	v	iv	7 lb. 4 oz.	4 hrs.		Large diaphragmatic hernia All abd. contents in chest	Yes
3	iv	ii	8 lb. 13 oz.		Previous stillborn; cause undetermined	Erythroblastosis fetalis (Died at University)	Yes
4	ii	i	7 lb. 2 oz.	1 hr.	Mild toxemia, Cesarian section, local anesthesia, follow by pentothal and ethylene	Asphyxia in utero	Yes
5	i	o	7 lb.	10 min.		Complete absence of diaphragm Abd. contents in chest cavity	Yes
6	iii	ii	6 lb. 4 oz.		No history of previous trouble	Hemorrhagic disease of the new-born	Yes
7	v	iii	5 lb. 9 oz.	36 hrs.	Previous ectopic pregnancy Cesarian section for placenta previa centralis at 8 mo.	Bilateral atelectasis due to aspiration of amniotic fluid	Yes
8	viii	vi	7 lb.	10 hrs.	One baby died of atelectasis	Atelectasis	No
9	i	o	6 lb. 11 oz.		Protruding eyes, no eyelids, no tongue, vocal cords in oral pharynx, extra digits on hands and feet.	Multiple malformations	No
10	viii	ii	7 lb. 8 oz.		Pt. over term. Instrumental rupture of membranes. Previous delivery stillborn, overdue.	Purulent pneumonitis	Yes

made with similar causes over the entire state. It will be noted that the percentages in each group in this hospital are not significantly different from those over the state. The neonatal death rate here over a two-year period has been 16.2 per thousand live births as compared with 18.9 for the state as a whole.

The conclusion inevitably reached from this study up to this point is that prematurity is the greatest problem in stillbirths and neonatal deaths. Careful consideration of the previously listed cases, however, reveals that the problem is probably not as great as it appears on the surface. It will be noted in this series that very few

TABLE V. PREMATURE NEONATAL DEATHS
1950-1951

Case	Grav	Para	Weight	Gestation Weeks	Pertinent Facts	Age at Death	Cause of Death	Autopsy
1	iv	ii	5 lb. 7 oz.	37	Previous stillborn. Medical induction because of increasing titre.	3 days	Erythroblastosis	Yes
2	xi	vii	1 lb. 2 oz.	22	Several previous abortions	30 min.	Prematurity	No
3	iii	ii	3 lb. 11 oz.	30	Premature separation of placenta. Transverse position.	3 hrs.	Premature separation of placenta. Anoxia.	No
4	xvi	x	1 lb. ½ oz.	22	Three previous abortions. Two previous premature del.	12 min.	Prematurity	No
5	i	o	3 lb. 1 oz.	26	No prenatal care.	4 hrs.	Prematurity	No
6	iii	i	13 oz.	26	Twin	8 hrs.	Prematurity	No
7	iii	i	12 oz.	26	Twin	8 hrs.	Prematurity	No
8	viii	vii	3 lb.	31	Breech, prolapse of cord.	½ hr.	Prolapsed cord.	No
9	ii	o	1 lb. 13 oz.	26	One previous stillborn. Mother diabetic, uncontrolled diet and insulin.	2 hrs.	Diabetes Mellitus	No
10	i	o	4 lb. 3 oz.	40	Clubbed feet, corneal opacity of left eye, agenesis of both kidneys, agenesis of rt. ventricle, incomplete separation of aorta and pulmonary artery.	25 min.	Multiple deformities.	Yes
11	iv	iii	2 lb. 14 oz.	28	One previous premature with death of infant.	4 hrs.	Prematurity	No
12	iv	i	3 lb. 4 oz.	31	Two abortions. Membranes ruptured at 4 months. Bleeding frequently since start of pregnancy.	36 hrs.	Prematurity	No
13	i	o	2 lb. 8 oz.	26	Twin. Hydramnios. Low forceps.	9½ hrs.	Prematurity	No
14	i	o	2 lb. 11 oz.	26	Twin. Hydramnios. Mid forceps.	9½ hrs.	Prematurity	No
15	vi	v	3 lb. 11 oz.	30	Membranes ruptured one month prior to delivery.	2 hrs.	Prematurity	No
16	ii	i	4 lb. 1 oz.	31	Bleeding during pregnancy.	10 hrs.	Prematurity. Marginal placenta previa.	No
17	i	i	1 lb. 2 oz.	20	Webbing of toes of right foot, absence of all toes of left foot.		Prematurity	No

TABLE VI. NEONATAL DEATHS 1950-1951

	Number Cases	Percent St. Gabriel	Percent State
Prematurity	11	44	35.5
Congenital Malformation	4	16	16.6
Birth injuries			17.5
Atelectasis	4	16	11.7
Pneumonia	1		
Asphyxia in utero	3		
Hemorrhagic disease of newborn	3	24	18.7
Diabetes Mellitus	1		
Death rate		18.1/M live births	18.9/M live births

autopsies were performed upon prematures, either in cases of stillbirth or neonatal death. This is unfortunate, and probably results in prematurity being listed as the cause of death in many cases where congenital malformations, atelectasis or other actual pathological conditions exist but are unrecognized and unproved. In the future, therefore, the high rate of autopsies that has been achieved in the full-term group should be carried over to the prematures, so that these deaths may be properly classified.

While it is difficult to list factors that will definitely lower the rate of premature deliveries, certainly adequate prenatal care is the best approach to the problem. Included in prenatal care, of course, are medical care, dietary control, proper housing, working conditions, recreational factors, and an adequate rest program. Studies that have been done on racial, economic, and sociological influences affecting the rate of premature births, indicate that if the above factors listed as adequate prenatal care are ideal, the premature rate will be significantly less.

The conduct of labor in the case of a premature delivery can definitely influence the survival rate of the premature infant. Since these infants are sometimes overly sensitive to sedation and general anesthetics given to the mother, these medications should be used cautiously. It is further known that these small infants are less able to withstand the trauma of a difficult second stage of labor. Therefore, the current teaching is to perform an episiotomy and deliver by forceps in many cases.

In this hospital these babies are placed in an incubator in the delivery room. Clearing of the respiratory passages is essential. Oxygen resuscitators are available in the delivery room. The presence of emergency bronchoscopic equipment and trained personnel is highly desirable and might possibly eliminate some of the respiratory deaths.

The actual nursing care and feeding program in this hospital is carried on according to the program recommended by the Minnesota Department of Health. The premature babies are attended only by highly trained personnel. This training program is a continuous one. Besides the faculty of St. Gabriel's Nursing School, specialists in the field of premature nursing have been called in from time to time to augment the training of the local faculty. Oxygen is administered from birth until the infant has progressed enough to be maintained without it. These babies are kept in incubators until they weigh at least five pounds. The premature survival rate is shown in Table VII.

TABLE VII.

1950

Total Premature Live Births

2 weighed less than 1 lb.; both died about 8 hrs. after birth
2 weighed between 1 and 2 lbs.; 1 lived 15 min.; the other lived 50 min.
1 weighed between 2 and 3 lbs.; discharged on the 79th day
5 weighed between 3 and 4 lbs.; 3 lived 30 min., 2 hrs. 40 min., and 4½ hrs,. respectively; 1 was discharged after 40 days; one after 85.
7 weighed between 4 and 5 lbs.; all lived.
9 weighed between 5 and 5½ lbs.; 8 lived, 1 died of erythroblastosis fetalis on 3rd day.

1951

Total Premature Live Births

1 weighed between 1 and 2 lbs. and died after two hours.
4 weighed between 2 and 3 lbs.; 2 (twins) died after 9½ hours; 2 were discharged after 44 and 51 days, respectively.
6 weighed between 3 and 4 lbs.; 1 died after 2 hours; 1 died after 36 hours; 4 were discharged after 29, 30, 48, and 51 days, respectively.
20 weighed between 4 and 5 lbs.; 1 died after 25 min.; 1 died after 10 hrs.; 18 lived.
17 weighed between 5 and 5½ lbs.; all lived.

Continuation of the high survival rate in the future assumes the continuation of the present excellent nursing care under supervision of the medical staff.

Congenital malformations are responsible for 16 per cent of neonatal deaths. More accurate diagnosis will undoubtedly increase this percentage. Nevertheless, the situation is not without some hope. Definite association has been shown between Rubella during pregnancy and congenital malformations. Nutritional factors certainly have some bearing on the subject. Physicians in rural practice will depend on the centers of learning for more information on this subject in the future. Hereditary factors undoubtedly play a large part. One of the neonatal deaths reported in Table IV was caused by a complete absence of the diaphragm. Recently, the wife of the mother's brother delivered an infant with the same defect. The recurrence of this defect in the same family would seem to be an hereditary defect rather than an accidental recurrence.

Birth injuries as a cause of stillbirths and neonatal deaths certainly are among the preventable causes of death, and one which should largely be eliminated. In the present series, there were two deaths that were at least partially caused by disproportion between the pelvis and the size of the fetus. Adequate measurement with x-ray mensuration in borderline cases and in those with obviously small measurements are easily obtained and should be required. In borderline cases a test of labor with prior preparation for section if necessary is probably the procedure of choice. Careful consideration should be given to the measurements of the mid-pelvis, since often the head may start to descend into the pelvis only to be held up when the operator may expect continued progress. Only by adequate measurements prior to the time of delivery may this situation be anticipated and injury or death to the baby be averted.

Consultation with specialists trained in obstetrics cannot always be obtained in this hospital because of the emergency nature of many of the complications and the distance to large medical centers. Nevertheless, in any case of inadequate pelvic measurements, with proper planning these patients may be seen by consultants so that help may be obtained in determining the type of delivery suitable.

In this group of cases, prolapsed cord has caused several stillbirths. This is always a serious complication and, according to DeLee it carries a 40 to 50 per cent mortality if treated and 80 per cent if untreated. The cord is not always palpable rectally, and if suspected, a vaginal examination should be done. The best treatment is immediate delivery of the child. If the cervix is not completely dilated, replacement of the cord above the head must be done. A vaginal bag or gauze pack may be used to advantage, together with the Trendelenburg position. Version may be used if the cervix is sufficiently dilated. Occasionally if the baby is in good condition, cesarian section may be indicated, particularly in older primiparae.

Atelectasis has previously been mentioned. Removal of fluids from the respiratory tract by suction with a catheter is usually sufficient. Bronchoscopy is highly desirable in some cases.

Pneumonia occurred in one case in this series. Antibiotics administered to those patients for whom labor is induced by rupture of the membranes is of value in preventing pneumonia in the infant.

Erythroblastosis fetalis is a definite hazard to those infants whose mothers have become sensitized. Proper prenatal care plus adequate transfusions seem at this time to be the best way of saving these infants. In the event the antibody titre is increasing, delivery two weeks prior to term is advisable. There is some disagreement on this point since the hazard of prematurity is added to that of erythroblastosis.

Summary

The maternal mortality at St. Gabriel's Hospital has been reviewed for the past ten-year period. The stillbirths and neonatal deaths have been reviewed for the past two years.

From this study, it can be concluded that this hospital is an extremely safe place for women to undergo childbirth.

From the stillbirth and neonatal standpoint, it compares about equally with the state as a whole.

As a result of efforts of some of the members of the medical staff, an eight weeks' course, one night a week, is now under way at this hospital. The course is being jointly sponsored by the Minnesota Department of Health and the Minnesota State Medical Association. The faculty consists of faculty members from the University of Minnesota and other obstetricians from the Twin Cities area. All the members of the medical staff of St. Gabriel's Hospital and several physicians from surrounding communities have attended.

The combined efforts of all these individuals, the nursing staff and administration of St. Gabriel's Hospital, should definitely result in further improvement in the stillbirth and neonatal death rate in this and other communities.

CHANGES IN THE MEMBERSHIP AND FELLOWSHIP STRUCTURE OF THE AMERICAN MEDICAL ASSOCIATION 1949-1952

1918 to 1949 Prior to 1950, and since the year 1918, all physicians who were active members of their State Society were non-dues paying members of the American Medical Association.

Of the 144,211 members of the A.M.A. in June, 1949, 77,723 were listed as fellows. Fellows paid dues to the A.M.A. and received *The Journal A.M.A.*

1949 The House of Delegates of the A.M.A. assessed all members of the A.M.A. $25.00, but this assessment was voluntary and not compulsory. This was the only *assessment* made.

1950 There was no assessment in 1950. The A.M.A., for the first time, set the dues for membership in the A.M.A. at $25.00 a year. If these dues were not paid by the end of the year the member was dropped for non-payment; before he could be reinstated, it was necessary for him to pay the delinquent year's dues.

The 1950 dues did not include a subscription to *The Journal A.M.A.*

A member in 1950 again had to pay fellowship dues to receive *The Journal A.M.A.*, or could subscribe to it separately.

1951 The membership dues in the A.M.A. in 1951 were $25.00 and included a subscription to *The Journal A.M.A.* Fellowship dues were reduced to $5.00 but no longer included a subscription to *The Journal A.M.A.*

1952 The same as 1951, except that there are no fellowship dues and fellowship cards are not being issued. Fellowship will probably be abolished after the Annual Meeting of the A.M.A. in June, 1952.

Case Report

ASPIRIN POISONING IN CHILDREN

W. RAY SHANNON, M.D.
Saint Paul, Minnesota

SERIOUS indictment is due the medical men of my generation for permitting the present casual attitude toward the indiscriminate use of salicylates to exist among the general population. We seem to have forgotten that in excessive doses it is a potent poison without an antidote and, once rampant, extremely difficult to combat. Now that in some form it is on every bedside table and in every medicine cabinet, frequently camouflaged and flavored so as to be most attractive to children, it is small wonder that instances of serious poisoning are being so frequently encountered by pediatricians. Aspirin, while not the most poisonous, is the most widely used salicylate compound and therefore figures most frequently, as in the present episode.

About 2:30 one afternoon, two sisters, aged two and one-half and four years, were found to have consumed from one-half to three-quarters of a bottle of aspirin. Originally, it had contained 100 5-grain tablets. Twenty minutes later they were at the Children's Hospital.

Large quantities of granular material resembling disintegrating aspirin tablets were removed from the stomach of the smaller child by repeated washings. When the mother revealed for the first time that the older girl had also been involved, a lesser amount of the same substance was washed from her stomach. Both appeared in the best of spirits after the manipulations, and the parents had to be persuaded to leave them in the hospital for observation.

Each ate a regular supper and nothing unusual was noticed until the younger one vomited her entire meal at 7:30 p.m. There was blood in the vomitus. The older child appeared normal at this time though later she did develop signs of mild poisoning.

When the vomiting, which had been projectile, was discovered the patient was found to be unconscious and extremely irritable, as evidenced by constant crying and ceaseless co-ordinated but purposeless movements of the entire body. The pupils were widely and equally dilated. The skin of the face and neck was peppered with small spots of ecchymosis. Extreme hyperpnea was present, and the mucous membranes and skin were a brilliant red, bringing to mind the vivid scarlet of carbon-monoxide poisoning. The child was soaked with perspiration. This critical picture persisted stubbornly in spite of all our efforts. Thirty-six hours passed before one could feel that recovery was assured.

Treatment was based upon the concept that in salicylate poisoning the basic assault is against the respiratory center and that it consists of a primary stimulation leading to respiratory alkalosis which is induced early and is maintained until elimination of the poison can occur. This takes place primarily through the kidneys. At some point, in the fatal cases at least, the alkalosis may be replaced by an acidosis. This poses a complicated clinical problem.

Oxygen in high concentration was administered until consciousness returned. Two cubic centimeters of parathyroid extract were given at once to minimize tetany and avert convulsions. A high fluid intake was essential and, since it was not held by mouth, it was given by clysis, both intravenous and subcutaneous, as one-half Ringer-lactate and one-half 5 per cent glucose in distilled water. Included with the clyses were the soluble B vitamins and ascorbic acid. Vitamin K was given repeatedly to maintain adequate prothrombin levels and prevent hemorrhage.

Shortly after the start of symptoms, the CO_2 combining power of the blood was 34 vol. per cent. The next morning it was 26. These results fitted the concept of respiratory alkalosis. Later, after the crisis was over, a value of 42 vol. per cent was obtained, which is normal in an infant.

For several days all samples of urine were examined as to pH, the presence of ketone bodies and salicylates. At no time did the pH vary beyond the limits of 5 and 6. This did *not* fit the concept of hyperventilation. Whereas consciousness returned early on the third day, salicylates continued to be excreted throughout the fifth day and ketone bodies were constantly present for another twenty-four hours.

Urinary glucose was present in substantial amounts throughout the fifth day, and on the second day, while the patient was still unconscious and while large amounts of acetone were appearing in the urine, the blood sugar was 130 mg.

Kidney irritation, as indicated by the presence of albumin, casts and both red and white cells, persisted until shortly before the patient was discharged on the eighth day. However, blood pressure and urea nitrogen values were normal.

The thirty-six-hour period from the beginning until the end of unconsciousness was as packed with confused anxiety as any I shall remember. Presumably the patient was in alkalosis, but clinically she looked like a person in severe acidosis. What tests were done carried no conviction either way and could not, even though it had been possible to regard them as anything more than a static measurement in a rapidly changing sequence. The possibility of an irreversible and fatal upset in acid-base equilibrium seemed constantly present, but whether alkalosis or acidosis was most to be feared was totally unclear. And that seems to package neatly just about all that can be gleaned, of immediate clinical value, from the vast accumulation of data dealing with severe and fatal salicylate poisoning.

In a large percentage of the fatal cases the actual cause of death has been obscured because of the presence of some previous organic disease. Perhaps we owe our good fortune here to the fact that our patient was so young and so organically sound.

Experiences such as this, and they are not rare, bring into sharp focus a neglected responsibility of the medical profession to make the lay public aware of the dangers in half-emptied aspirin bottles just lying around—just lying around (that is) where children run around.

Read before the Ramsey County Medical Society, Saint Paul, Minnesota, April 28, 1952.

NOTES ON THE HISTORY OF MEDICINE IN WASECA COUNTY PRIOR TO 1901

B. J. GALLAGHER, M.D., and J. F. LYNN, M.D.

Who owned the land that is now Waseca County, in fact all of Minnesota west of the Mississippi River, previous to the coming of the first white settlers? Of course, the United States acquired it from France in the Louisiana Purchase in 1803, but it is not likely that the Indians who lived here ever heard of the Louisiana Purchase, nor even of France. They must have considered that they owned it. The Federal Government paid at least lip service to this claim in 1851 when, at Traverse des Sioux and at Mendota, treaties were made with the Indians by which for an eventual payment of two cents* an acre, they gave up millions of acres of excellent land, and consented to move west to reservations along the Minnesota River. After the treaties were ratified, land offices were opened and the land between the Mississippi and the reservations was legally opened to settlement. The lands in southeastern Minnesota closest to the Mississippi naturally were settled first, but by 1853 there were settlers along the Straight River at the site of the present city of Owatonna. For a wonderfully comprehensive history of the process of settlement of southeastern Minnesota during 1851 and after, as well as the early history of medicine in Minnesota, the reader is referred to the articles by Nora Guthrey, which ran serially in Minnesota Medicine from 1945 to 1951, on the "History of Medicine in Houston, Fillmore and Olmsted Counties Prior to 1900."

Previous to February 20, 1855, the western two-thirds of what is now Steele County and all of what is now Waseca County formed part of Rice County. On that date Steele County was created by the Territorial Legislature. The territory embraced in the new Steele County consisted then of all the present Waseca County and the western two-thirds of the present Steele County. The eastern one-third (present east tier of four townships) of Steele County was then a part of Dodge County. Owatonna was then only one or two years old, and was the county seat, but was unfavorably located to retain this position as it was very near the eastern border of the county. In February, 1856, the Territorial Legislature detached the western tier of townships from Dodge County and made them a part of Steele County. On February 27, 1857, an act was passed by the legislature creating Waseca County by cutting off from Steele County a strip eighteen miles from east to west. This resulted in the three counties of Dodge, Steele and Waseca, all of equal size, eighteen miles from east to west and twenty-four miles from north to south. It also assured to Owatonna the retention of the county seat of Steele, since it was now more nearly in the center. Strangely enough, many of the comparatively few settlers in the new county of Waseca were not in favor of the new arrangement because, besides being the most sparsely settled, a considerable portion of the new county (about one-fifth) was in the Winnebago Indian Reservation and therefore not open to settlers.** The settlers were not anxious to take over the expense of starting a new county while the population was so small.

---

*The treaty stipulated 10c per acre.

The county seat was located at Wilton until such time as an election could be held. The Territorial Governor (Gorman) appointed three commissioners, a sheriff, a register of deeds, and two justices of the peace to serve until the first election. There were of course as yet no townships, but five voting districts were set up and an election was held on the first Monday in June, 1857. At this election a full slate of county officers was elected and Wilton, the largest village in the county, was chosen as county seat. The town of Waseca was not to come into existence until ten years later, in the fall of 1867, when the Chicago and Northwestern Railroad reached that area. Wilton was four and a half miles southwest of Waseca, and since the railroad missed Wilton, Waseca quickly outgrew it. In 1869 another election was held and Waseca became the county seat. During the next few years the old town of Wilton gradually went out of existence.

The first settler in the present Waseca County (then still a part of Rice County) was Mr. Asa G. Sutlief, who came with his wife and two children in a covered wagon in August, 1854. With him he had sixty sheep and about thirty head of cattle. Three hired men accompanied him. He had the choice of any land that he wanted. He selected some land on a bend of the Le Sueur River, at a point about four miles south of the site, also on the river, which within a year or two was to become the village of Wilton. One speculates that he selected this site because it had water and wood and an abundance of rich prairie land to the south and west. He erected a cabin, broke up a few acres of sod, put up some hay and hired a man to stay there to care for the stock. In November he and his family returned to Wisconsin. He came back in January of 1855, his family joining him later in the year. During 1855 and especially during 1856, many more settlers came and, as previously stated, in 1857 the County of Waseca was set off from Steele County.

The Winnebago Indians were not as warlike as the Sioux and did not join in the outbreak against the white settlers in 1862. Nevertheless, the Government moved them west to Montana in 1863.† That part of Waseca County which had been in the reservation, was then thrown open to settlement. Many new settlers came from Wisconsin and other places that year. The early settlers in the county were largely German, Norwegian, Swedish and Irish, with a good sprinkling of "Yankees" from New England and other places in the east.

Medical History

A state territorial medical society was organized in 1853 but held only two meetings. It was reorganized in 1856, but seems to have folded up again. The present State Medical Society was organized (or reorganized) in 1869. Before that there was no medical practice act, and anyone who claimed to be a doctor was not disputed. On March 4, 1869, the legislature passed a lax medical act requiring a diploma as evidence of fitness to practice medicine, but at that time there were many homeopathic and eclectic as well as regular (allopathic) schools and associations, which could and did issue diplomas freely. Often the diploma did not signify much training or capacity to practice medicine. As the act seemed to compound the evil it was repealed in a year or two. Then in 1883 the first real medical practice act was passed and under it the Board of Regents of the University was the medical board. Licenses, to the number of 1501, were granted by this

---

**The Indian Reservation covered two whole townships and part of two other townships.

†The movement started officially on May 9, 1863, with three steamers taking the Indians as far as Fort Snelling. There they gradually moved to the region of Omaha. This is not perfectly certain, however.

Board, 1325 of them to holders of diplomas from recognized medical schools, 33 after examination and 143 by "Exemption Certificates," these doctors having produced evidence that they had practiced in Minnesota for five years or more prior to the passage of the act.

In 1887 a new act was passed providing for a nine-man examining board, as diplomas from supposedly reputable schools were often held by incompetent men. In and after 1887 new applicants for licenses had to take an examination, except that a few who had not complied with the law of 1883, but had five or more years of practice were licensed "by exemption."‡

In 1890, after this Board had been functioning for three years, it published an "Official Register of Minnesota Physicians, 1883-1890" listing all doctors in active practice at that time. It gave the number of each man's license, by what method he was licensed, his school, date of graduation, whether "regular" or "homeopath" et cetera, as well as the date his certificate was issued. The following doctors were listed as practicing in Waseca County, during at least some part of that time (1883-1890):

License No.	*Name*	*School of Practice*	*Location*
381	Christie, Geo.	Regular	Waseca
787	Craig, R. O.	Regular	Janesville
380	Cummings, Damon S.	Regular	Waseca
1119	Hubbard, Wm. E.	Regular	Waseca
511	Hunt, M. V. (listed as having left the state recently)	Regular	Waseca
1053	Hutchinson, A. M. (listed as having moved from state)	Homeopath	Waseca
796	Lang, Wm. A.	Regular	New Richland
746	Remington, Chas. I.	Regular	Alma City
1317	Swartwood, Frederick A.	Regular	Waseca
549	Taylor, Martin J.	Regular	Janesville
Exemption	Young, H. J.	Regular	Waseca

Under this act of 1887, it was also required that each doctor register his license certificate with the Clerk of Court in the county where he practiced. This apparently was not universally done at first as the names of at least three or four doctors who are known to have practiced in Waseca County are missing from the following list, procured from the records of the Clerk of Court up to and through 1900:

Date of Filing	*Doctor's Name*	*Date of Certificate*
12- 5-1883	Damon S. Cummings	11-24-1883
1- 2-1884	M. V. Hunt	12-28-1883
1- 2-1884	Martin J. Taylor	12-31-1883
1-26-1884	Charles Remington	1-16-1884
4- 5-1884	David W. Horning	1-28-1884
4-14-1884	William A. Lang	2- 6-1884
6- 5-1884	John Nutting	5-28-1884
5-15-1885	Attila M. Hutchinson	5-13-1885
3- 8-1887	Frederick A. Swartwood	3- 7-1887
3-19-1888	Eugene Hubbel	2-18-1884
7-12-1890	Frank W. Green	3-12-1887
6-10-1892	Fred N. Hunt	4- 8-1884
10-18-1892	Joseph Parker Corry	10- 7-1892
5- 3-1893	Clinton F. Cook	7- 8-1892

---

‡The law provided that the applicant present satisfactory credentials of having graduated from a reputable medical school and proof of having practiced in the State of Minnesota prior to July 1, 1887. The period of five years' practice may have had a part in granting a license though the law does not mention it.

7-12-1894	James B. Lewis	11- 7-1885
7-23-1894	Delos Dewitt Smith	7-10-1894
8- 6-1895	Edwin J. Batchelder	10- 6-1895
5-11-1896	James H. Bowers	3-30-1885
6-17-1896	Franklin T. Poehler	6- 9-1896
7-28-1896	H. P. Dredge	6- 9-1896
No Date	C. E. Backman	4-14-1896
3-10-1896	Dennis J. McMahon	1-14-1896
7- 8-1899	Wm. Davidson Rea	6-16-1898
8-15-1899	Wm. A. Chamberlain	3-15-1883
8- 7-1900	L. E. Kuchenbecker	10-12-1893

The following doctors are known to have practiced at the time or after the time of the law of 1887, but apparently never registered with the Clerk of Court:

R. O. Craig
Henry J. Young
George Christie
R. N. Sackett
W. L. Sterns
J. A. Reynolds
Wm. E. Hubbard
Norman C. Davis

The following doctors are known to have practiced in the county and either died or left the county, previous to the medical practice act of 1887:

William Murphy
M. S. Gove
B. M. J. Conlin
Jacob C. Brubaker
F. C. Peck
H. T. Cobb
L. D. Pierce
L. D. McIntosh
Dr. Palmer

Some who practiced previous to 1901 and were still in practice in the county after 1901 registered later and are as follows:

6-16-1902	James F. Lynn	10-11-1900
6- 1-1909	J. J. O'Hara	10-11-1898
5-16-1917	Henry G. Blanchard	6-10-1897

Undoubtedly there were many practitioners of one kind and another who came and went in the early years of whom there is no record available. The early settlers were glad to avail themselves of anyone who thought he could help and was willing to try.

The charter of the present Waseca County Medical Society is dated 1904. However, the June 16, 1869, issue of the *Waseca News* contained the following article:

Medical Society

"Doctors Craig, McIntosh, Brubaker, Young and Gove met at Waseca, June 5, 1869, and organized a medical association, to be known as the Waseca County Medical Society. Dr. R. O. Craig of Janesville was elected president, and Dr. D. L. McIntosh of Waseca was elected secretary. Drs. Gove and McIntosh were elected delegates to the State Medical Society. The association adjourned to meet the first Tuesday in July."

How long this society existed is not known, but apparently it quit functioning long before 1904. If others existed in the interim no mention has been found of them.

Many of the doctors belonged to the Minnesota Valley Medical Society, which was organized in 1881, and the Southern Minnesota Medical Society which started in 1892. They merged in 1913 as the present existing Southern Minnesota Medical Society.

No regularly established hospital is known to have existed in the county until

February, 1922, when the Waseca Memorial Hospital, newly constructed, was opened for occupancy with a capacity of twenty-five beds and ten bassinets. For a few years before that local doctors occasionally took patients to the Owatonna City Hospital for operation. After about 1884, when surgery began to develop, surgeons from out of town, usually Mankato or Rochester, sometimes were called in for emergency operations in the home or in the doctor's office.

The first regular physician in Waseca County has always been said to have been M. S. Gove, who came to Wilton in 1858, and who died in Waseca in 1874. However, William Murphy came to Wilton in 1857, in poor health, and he died early in 1859. He probably never practiced very much and is known to have taught for a time in a private school, the "Wilton Seminary," which opened in 1858 and closed for all time in 1861. The biographies of the doctors, such as are available, are listed below in alphabetical order:

Clarence E. Backman, a homeopathic physician, was graduated from Barnes Medical College, St. Louis, in 1894. His certificate to practice in Minnesota was dated April 14, 1896. He was in Waseca for a year or two after that, but by 1898 he had moved to Minneapolis, where he had an office at 2423 Central Avenue N.E. He was there until about 1902, when he located in Evansville, Douglass county.

Edwin J. Batchelder was born in Osceola, Wisconsin, April 17, 1866. The family moved to Stillwater, Minnesota, when he was a small boy. His father was a boat builder and as a boy in the grades the young Ed had to go right home after school, change his clothes, go down to the boatyard and spin oakum. As he got older, he spent his summers painting boats. Later, after some college work, he taught Latin in the Stillwater High School, from which he had graduated earlier. He studied medicine at the University of Minnesota, graduating in 1895. At one time, during his student days, he won a set of books donated by the Mayo Brothers as a prize in surgery.

He started practice in New Richland, Waseca County, in the fall of 1895, and spent all but the last two years of his life there. In 1898, he was elected Coroner and several times he was president of the Waseca County Medical Society.

A few years after coming to New Richland he married Miss Lillie Lofty of that town and they were the parents of two daughters. The older one, Alice, became a medical technician and worked in hospitals in Memphis, Tennessee, and Newark, New Jersey. She married Lester Johnson, a chemical engineer, and they have two boys and one girl. They live in Loripoc, California. The younger daughter, Helen, married Robert Fisher of Anderson, Indiana, and they have three daughters. Mr. Fisher is with an advertising agency in New York City, and they live in Plainfield, New Jersey.

In 1918 Dr. Batchelder moved to Minneapolis, where he became associated in practice with Dr. F. W. Schlutz, an old New Richland boy, who was then an eminent children's specialist on the faculty of the University of Minnesota. Dr. Batchelder died after a short illness on September 30, 1920, at Abbott Hospital, Minneapolis. He was buried at Stillwater, Minnesota.

He was so well thought of at New Richland that twenty years after he left there and eighteen years after his death, a memorial service was held in the High School Auditorium, on December 29, 1938. A beautiful bronze memorial plaque, bearing a portrait of the Doctor and a suitable inscription, was presented to the school by the citizens of the town. The *New Richland Star* at that time said "During his stay in New Richland, Dr. Batchelder became the true and trusted friend of every one with whom he came in contact. He typified all that was good and noble in the role he played as family physician."

After Dr. Batchelder's death, Mrs. Batchelder taught piano in the MacPhail School of Music, Minneapolis, for fifteen years. Now (1952) she lives in Bound Brook, New Jersey, where she has taught music since 1937.

J. P. Berrington's card first appeared in the Waseca paper on October 25, 1871, stating that his office was in his house at Wilton. This was two years after Wilton lost the County seat and Dr. Gove moved into Waseca. His card appeared for the last time on April 1, 1874. Nothing more is known of him.

Henry G. Blanchard, who died April 13, 1945, at the Fairmont Community Hospital, the institution he had helped to found in 1937, had a lifetime of pioneering in southern Minnesota. The doctor's parents, Gustave and Anna Marie Blanchard, natives of Switzerland, the father of French ancestry and the mother of German, arrived in southeastern Minnesota in the late 1850's, just as the state was emerging from a territory into statehood. They were married before emigrating to America. For a short time they stopped in Ohio, then pushed on across the Mississippi and established themselves in Winona County. There their son, Henry, was born April 17, 1868.

There were twelve children in the Blanchard family of whom the doctor was the eighth. In early life, he became familiar with all the hard work incident to pioneer life and the development of a farm from wilderness soil. He attended rural schools in Winona County, also in Cass County, North Dakota. Some of the terms were in a little log school house, and he remembered best the famous Blue Back Speller of that era. Later he attended the Winona High School and in 1893 obtained his B. S. degree at the University of North Dakota. He then attended the University of Minnesota, where he was awarded the degree of Doctor of Medicine in 1897. He first practiced at Hutchinson, Minnesota, then settled in Waseca in 1899 and practiced there for nearly three decades. Not until 1920, did Dr. Blanchard take a vacation, when he turned over his practice to Dr. Miller and spent a year in California. He and Dr. Miller then entered into partnership in Waseca. They went to Fairmont in 1928 and with others organized and built the Fairmont Clinic and Hospital, now the Community Hospital. With this institution Dr. Blanchard was associated the remainder of his life.

He was a member of the Blue Earth Valley, the Southern Minnesota, the Minnesota State, and the American Medical Associations. In the first World War, he volunteered in the Medical Corps in which he held a reserve commission, but was not called to active service because of the great need for his services on the home front. He was the medical examiner of the Waseca County Draft Board for a time. At Waseca he held many positions of official trust and responsibility and was the first citizen to own and drive an automobile.

The marriage of Dr. Blanchard and Miss Katherine Kiesler occurred at Hutchinson, Minnesota, June 25, 1902. They had a son, George H. Blanchard. Mrs. Blanchard's death occurred September 25, 1940.

Funeral and burial of Dr. Blanchard in Fairmont's Lakeside Cemetery took place the day before the doctor's seventy-seventh birthday, on April 16, 1945. He was a Democrat in politics, and was affiliated with the Episcopal Church. Dr. Blanchard was one of the kindliest, most considerate of men—qualities that endeared him to all.

James H. Bowers filed his medical certificate, which is dated March 30, 1885, with the Clerk of Court in Waseca County on May 11, 1896. He was a homeopathic physician and apparently did not stay in Waseca very long. The notes on the "Medical History of Nicollet County," in the May, 1949, issue of MINNESOTA MEDICINE, has this brief account of him: "James H. Bowers was graduated from the Chicago Medical College in 1885. He practiced homeopathy, locating in St. Peter in May 1891, and remaining until January 1894, when he moved to Renville, Iowa. From 1897 to 1899, he was in Owatonna." It seems probable that he moved to Owatonna after about a year in Waseca. Nothing more is known about him.
